COURSE AND MANAGEMENT OF MYASTHENIA GRAVIS

David Grob, M.D., Baltimore, Md.

Since myasthenia gravis is a disease that is subject spontaneous remissions and exacerbations, it is diffi- lt to evaluate the effect of procedures that are intended alter the course of this disease. There has been con- derable difference of opinion concerning the effect of ymectomy[1] and of irradiation of the thymus.[2] Pre- minary observations on the effect of thymectomy sug- sted that the rate and degree of remission following is operation were greater than would be expected to ccur spontaneously.[3] Because 12 years have elapsed nce these observations were begun, a review of this oblem, in which the course of patients who have had ymectomy or irradiation of the thymus are compared ith patients of comparable severity of illness who have d neither procedure, seems appropriate.

A total of 202 patients with generalized myasthenia avis have been studied in the Johns Hopkins Hospital om 1 to 34 years, the average being 8 years. Sixty-one er cent of these patients were women. Onset of the dis- se was at a lower age in the women, whose average e was 28, than in the men, whose average age was 43 onset. Of 27 patients in whom the disease began before e age of 17, 23 were female.

COURSE AND REMISSION

It is well known that the course of myasthenia gravis quite variable. Approximately one-fourth of the pa- ents studied (46) have had complete or nearly com- lete remission of their generalized myasthenia gravis t some time during its course, as manifested by complete r nearly complete disappearance of signs and symptoms f the disease for at least six months. Forty-two patients ave had only one remission; four patients have had etween two and four. The length of the remissions has een variable but has been as long as 17 years and has veraged 4.6 years. Approximately one-third of the emissions began during the first half year after onset of ymptoms, and one-half began during the first year. The average time interval between onset of the disease and remission was four years.

The administration of neostigmine bromide did not appear to influence the incidence or duration of remission. During the first half year after onset of the disease almost all of the remissions began while the patients were not receiving neostigmine; after this time most of the remissions began while the patients were receiving the drug. But this fact merely reflects the time after onset of the disease that drug administration is ordinarily begun for symptomatic relief. The average length of therapy with neostigmine was 2.7 years. The average duration of remission was approximately the same in patients who had taken neostigmine as in those who had received none, and it was about the same in patients whose remission began early in the disease as in those whose remission began late.

Thirty-two per cent of the patients with generalized myasthenia gravis died of the disease between 3 months and 24 years after onset, the average being 6 years (table 1). During the course of the disease these patients who died had only one-third the incidence of spontaneous remissions as the patients who are still alive and who have been followed for only a slightly longer period of time (8 years). Thirteen per cent of the total number of patients are in a complete or nearly complete remission at the present, 1 to 34 (average 8) years after onset of the disease, 25% have improved to a moderate degree, 20% are unchanged, and 10% have become worse. In general, the disease tended to run a more prolonged course in women, and the female patients have had a somewhat lower mortality rate than the male.

THYMECTOMY AND IRRADIATION OF THYMUS

Forty-four patients, 19 men and 25 women, were subjected to thymectomy 2 to 12 (average 6) years ago (table 2). The average severity of disease at the time of operation was slightly greater than in the other pa-

[3] Footnotes 1*a*, *b*, and *c*.

tients with myasthenia who were hospitalized but who did not have thymectomy or irradiation. The average duration of the disease at the time of operation was 3 years, and one-third of the patients were operated on during the first year of their illness. The average age at the time of operation was 37 years for the male patients and 29 for the female. The average duration of neostigmine therapy prior to operation was less than a year and a half. The course of the patients who had thymectomy performed has been, in general, only slightly better than the course of those who had neither thymectomy nor irradiation. Approximately the same proportion of patients have died in each group, and the proportion of patients who have had remissions is also similar. A slightly higher proportion, particularly of the female patients, have improved, and fewer patients have become worse since thymectomy, but the difference is disappointingly small. The course of the female patients after thymectomy has been slightly better than that of the male, but this is also true of the patients who were not operated on. The incidence of improvement following thymectomy has been greater in young female or male patients than in older patients, but this, again, is also true of the patients who were not operated on, and there does not appear to be any striking difference between the two groups.

Table 1.—*Course of 202 Patients with Generalized Myasthenia Gravis*

	No. of Patients	Age at Onset, Yr. (Avg.)	Duration of Myasthenia Gravis, Yr. (Avg.)	In Remission, %	Improved, %	Unchanged, %	Worse, %	Dead, %
Male	79	42	7.2	14	20	18	10	38
Female	123	28	8.8	12	28	22	11	28
Total or Average	202	33	8.2	13	25	20	10	32

Forty patients have had irradiation of the thymic region with about 2,000 r. A somewhat higher proportion of these patients have improved since irradiation, and a smaller proportion have died, but, on the other hand, fewer have gone into complete remission and the difference from the control group is not striking (table 2).

Table 2.—*Effect of Thymectomy and Irradiation of Thymus on Course of Myasthenia Gravis*

Sex	Procedure	No. of Patients	Duration of Myasthenia Gravis, Yr. (Avg.)	In Remission, %	Improved, %	Unchanged, %	Worse, %	Dead, %
Male								
	None	41	7.2	17	12	12	15	44
	Thymectomy	19	7.2	22	16	21	0	42
	Irradiation	19	7.2	0	42	26	10	21
Female								
	None	77	9.0	14	22	22	12	30
	Thymectomy	25	9.7	12	36	24	0	28
	Irradiation	21	6.8	5	38	19	19	19

In most of the patients who improved after thymectomy or irradiation, improvement began within several weeks after the procedure. In several patients improvement was dramatic and has been maintained for many years; however, in a larger number of patients improvement did not occur or was transient. It is difficult to know to what extent beneficial effects that followed either procedure may be attributed to the procedure itself, to concomitant encouragement of the patient or to other psychological effects of a treatment that is intended to alter the course of the disease and to which subsequent spontaneous improvement would be attributed.

THYMIC HYPERPLASIA AND THYMOMA

Nine of the 44 patients who had their thymus removed were found to have thymomas. The others had varying degrees of hyperplasia of the thymus without tumor formation, except for five patients who had what was regarded as a normal thymus for their age and two patients who had no detectable thymus in the fatty tissue that was removed. Of the nine patients who had thymomas removed, six have died of myasthenia gravis. Four other patients who were not operated on and who had a rapid, fulminating course terminating in death were found at post mortem to have thymomas. It would appear from these observations that myasthenic patients who have thymomas are more likely to have a severer form of the disease and a poorer prognosis, regardless of whether thymectomy is performed. However, two of the patients who are still alive and who have had a relatively benign course of many years' duration have roentgenographic evidence of a rounded mass in the anterior mediastinum that very likely is a thymoma. One of the two patients who had no detectable thymus tissue removed at operation has had progressive and moderate improvement in his myasthenia gravis during the seven years that have elapsed since operation, and the other has improved slightly.

Table 3.—*Course of Forty-Eight Patients with Localized Ocular Myasthenia Gravis*

	No. of Patients	Age at Onset, Yr. (Avg.)	Duration of Myasthenia Gravis, Yr. (Avg.)	In Remission, %	Improved, %	Unchanged, %	Worse, %	Dead, %
Male	26	40	8.3	12	15	65	8	0
Female	22	29	8.8	36	9	50	5	0
Total or Average	48	85	8.5	23	13	58	6	0

LOCALIZED OCULAR MYASTHENIA GRAVIS

Forty-eight patients in the group studied have had myasthenia gravis localized to the extraocular muscles during their entire period of observation (except, in most instances, for concomitant weakness of the orbicularis oculi) (table 3). This is one-fourth the number of patients with generalized myasthenia gravis who were seen. In contrast to the higher incidence of generalized myasthenia in women, localized ocular myasthenia was commoner in men. In both groups of patients the average age of onset was higher in men. The patients with ocular myasthenia have been followed from 1 to 41 years, the average being 8½ years, without any evidence of extension of the disease. In most, the disease has been relatively unchanged since onset, and in almost all the others some degree of improvement has occurred during the period of observation, with about one-fourth being in remission at the present time. Two of the patients with ocular myasthenia had thymectomy performed seven years ago, and three had irradiation of the thymus, without any discernible effect on their disease.

EXTENSION OF LOCALIZED OCULAR MYASTHENIA GRAVIS

When a patient who has localized ocular myasthenia gravis is examined, the question arises as to the likelihood of extension of the disease to other muscles. Examination of the course of the 202 patients with generalized myasthenia gravis is of interest in this regard. Of these 202 patients, generalized symptoms developed in 40% within 1 month after onset, but 34% had only ocular manifestations for 1 or more months after onset, 15% had their initial symptoms confined to the extremities for this period, and 11% had only bulbar symptoms during this period (table 4). In 69 patients generalized myasthenia gravis developed after they had had localized ocular myasthenia between 1 month and 24 years. Extension of the disease occurred after 1 to 6 months of ocular myasthenia in over half of these patients and after 1 to 12 months in over three-fourths. In only 11% of the patients was there extension of the disease after 2 to 5 years of localized ocular myasthenia, and there was extension of the disease in the same proportion of patients after 6 to 24 years. Therefore, a patient who has had localized ocular myasthenia for more than two years probably has a good chance of not having further extension of the disease, though in a proportion of such patients generalized myasthenia gravis will eventually develop.

TABLE 4.—*Signs and Symptoms During First Month of Generalized Myasthenia Gravis*

	No. of Patients	Generalized, %	Ocular Only, %	Extremities Only, %	Bulbar Only, %
Male	79	43	36	11	10
Female	123	38	32	10	20
Total or Average	202	40	34	11	15

MANAGEMENT OF GENERALIZED MYASTHENIA GRAVIS

The management of patients with generalized myasthenia gravis still relies heavily on neostigmine. Careful administration of one of the stronger and partly irreversible anticholinesterase compounds, such as tetraethylpyrophosphate (TEPP) [4] or octamethyl pyrophosphoramide (OMPA),[5] results, in most patients, in more sustained strength and better endurance than is possible with neostigmine, but the maximum strength attainable with any of these drugs, or with their combination, is approximately the same. Patients who show little gain in strength after large doses of neostigmine bromide are helped but little by TEPP or OMPA or by an even more potent organic phosphate anticholinesterase compound that has recently been studied. The organic phosphate anticholinesterase agents have the disadvantage that excessive doses may result in weakness much more readily than in the case of neostigmine. In addition, OMPA has the disadvantage of having a latent period of several hours before the action of any given dose is manifest. The latent period is reflected by the time interval between administration of this compound and depression of cholinesterase activity of the plasma and red blood cells and is apparently due to the time interval required for conversion of OMPA, which does not itself have anticholinesterase activity, to an anticholinesterase compound of unknown constitution, presumably by the liver. The regulation of myasthenic patients receiving OMPA is slower and more difficult than is the case with TEPP, and this tends to outweight to some extent the advantages that OMPA has over TEPP in relation to its greater stability in solution and its less marked central neural effects.

When the muscles of respiration and of swallowing are seriously affected by myasthenia gravis and do not respond adequately to neostigmine, use of the respirator and of tracheotomy have become lifesaving. While many patients die in the respirator because of respiratory obstruction or of other causes, which are not clear, some have been kept alive in the respirator for as long as 6 to 12 months. Four such patients subsequently have been able to leave the respirator for several months, and one has had a moderate remission that has enabled her to return to full-time household duties for the past two years. This example emphasizes that the myasthenic process may improve spontaneously, even after it has reached a very severe stage, and emphasizes the need for careful management of the patient through every crisis, in the hope that some degree of spontaneous improvement may occur. The occurrence of spontaneous improvement in some patients who have been through a severe myasthenic episode illustrates the difficulty that exists in evaluating the occurrence of improvement following thymectomy, which is frequently followed by several days of increased weakness and increased requirement for neostigmine.

Since it does not seem to be possible to influence the course of myasthenia gravis in a predictable manner by means of thymectomy or of irradiation of the thymus, and since even the most potent anticholinesterase compounds available have very definite limitations in situations in which the need for help is greatest, namely in patients who are responding poorly to massive doses of neostigmine, other approaches to this problem must be sought. The most promising lines of investigation seem to be study of the relation of myasthenia gravis to the glands of internal secretion and study of the underlying defect in neuromuscular function. With regard to the former it is of interest that exacerbation of the disease may occur prior to the onset of the menstrual period, following parturition, or following the administration of thyroid hormone, of corticotropin (ACTH), or of cortisone.[6] With regard to the latter it is of interest that the defect in neuromuscular conduction, which is characteristic of myasthenia, can be corrected transiently by the intra-arterial injection of an appropriate amount of acetylcholine,[7] the presumed mediator of neuromuscular conduction. This fact suggests that the defect in this disease may be related to either deficient synthesis or release of acetylcholine at the neuromuscular junction or to diminished sensitivity of the receptor substances to this compound. Since preliminary observations indicate that most myasthenic subjects have normal reactivity to acetylcholine,[7] the available evidence seems to support the possibility of deficient synthesis or release of this compound and to emphasize the need for more intensive study of the acetylcholine cycle in voluntary muscle.

SUMMARY

Of 202 patients with generalized myasthenia gravis who have been followed in the Johns Hopkins Hospital for 1 to 34 (average 8) years, 32% have died within an average of 6 years after onset, 13% are in complete or nearly complete remission, 25% have improved to a moderate degree, 20% are unchanged, and 10% have become worse. One-fourth of the patients have had complete or nearly complete remission of their disease at some time during their course, with the average length of remission being 4.6 years.

The course of 44 patients who were subjected to thymectomy and of 40 patients who had irradiation of the thymus was, in general, only slightly better than the course of 118 patients who had neither procedure. Fifteen patients had a thymoma. Ten of these patients had a rapid, fulminating course terminating in death, regardless of whether thymectomy was performed.

When localized ocular myasthenia gravis became generalized, it usually did so within the first year of the disease. The majority of patients who have had localized ocular myasthenia for more than one year have not had further extension of the disease during a period of observation of 1 to 41 (average 8½) years. The maximum strength attainable with tetraethylpyrophosphate (TEPP), octamethyl pyrophosphoramide (OMPA), or neostigmine bromide, or with their combination, has been approximately the same, but TEPP or OMPA have provided somewhat more sustained strength and better endurance than neostigmine bromide in most patients.

MECHANICAL ASPECTS AND SURGICAL MANAGEMENT OF STERILITY IN MEN

Vincent J. O'Conor, M.D., Chicago

This paper is concerned with a study of 123 patients who had complete azoospermia and in whom either exploration of the scrotal content or corrective surgery was performed. These patients were, of course, selected from a larger group of persons seeking the cause and cure of their sterility. Some of these patients were seen as long as 33 years ago and some during the past few months.

CAUSES OF STERILITY

Mechanical obstruction or lack of continuity of the vasoepididymal ductal system is the result of (1) incomplete or improper development of the ductal system itself, (2) obstruction in the epididymis or in the vas as a result of postinflammatory constriction and occlusion of the lumen or the ejaculatory ducts, and (3) inadvertent or purposeful division of the vasa.

The records show that, in these 123 patients, azoospermia, as nearly as it could be defined, was due to many factors. 1. Bilateral congenital absence of the epididymis caused sterility in two patients. 2. Bilateral failure of anatomic union between the vas and the epididymis caused it in four patients. 3. Unilateral atrophy of testis (postmumps orchitis) with congenital absence of the epididymis and vas on the side of the normal testis caused it in two patients. 4. Bilateral absence of both vasa with anomalies of the epididymis was the cause in three patients. 5. Previous epididymectomy on one side without union of the vas and epididymis on the other side resulted in sterility in one patient. 6. Inadvertent, bilateral surgical ligation of the vasa deferentia during operation to repair inguinal hernia or correction of hydrocele and/or varicocele caused it in seven patients. 7. Surgical division of the vasa deferentia for purposes of sterilization had been performed in 35 patients. 8. Sterility followed bilateral vasostomy with injection of the vas (after the method of Belfield) in eight patients. 9. Sixty-one patients were sterile because of previous bilateral epididymitis, the exciting cause having been either the gonococcus or some so-called nonspecific, pyogenic organism.

Congenital maldevelopments of the vasoepididymal tract have received scant attention in both the anatomic and urological literature. I am convinced from my own experience that these anomalies are much commoner than has previously been supposed. Michelson in a recent report states that, in a series of over 2,100 patients with subnormal semen, diagnosis of obstruction of the duct was made in 5%. In this group, he discovered unilateral maldevelopment of the vasoepididymal duct in 3 patients and bilateral maldevelopment in 17 patients. This is by far the largest personal observation of these anomalies ever recorded clinically.

It should be emphasized that in my study there was never any evidence found to suggest that obstruction of the vasoepididymal duct system, in itself, was the cause of pathological changes in the structure or function of the testis. When a pathological process in the testis is associated with ductal blockage, it is caused by some other systemic or local disease.

The pathological change usually consists of an obstructive lesion composed of fibrous tissue, the areas being single or multiple, either confined to the lumen of the vas in its scrotal or inguinal portion or, more commonly, to the lower portion of the globus minor and the most proximal portion of the vas. The area of obstruction in the vas becomes a solid cord of fibrous tissue,

---

Read in the Symposium on Fertility before the Section on Urology at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

From the Department of Urology of Northwestern University Medical School and Wesley Memorial Hospital.

with no evidence whatsoever of an epithelial lumen. The sheath surrounding the vas is often markedly thickened and contains dilated lymphatic and venous channels.

SURGICAL CORRECTION

In contemplation of the possibility of surgical correction of azoospermia, a very careful history of the underlying problem should be obtained together with an investigation of the psychic elements concerned with the sterile marriage before any optimistic outlook as to improvement is offered. Testicular biopsy may be indicated, but in most instances the greater knowledge that may be obtained by scrotal exploration and direct examination is preferred.

Operation to relieve vasoepididymal obstruction is indicated only in the presence of a normally functioning testicle. Preoperatively the condition of the testis can be accurately diagnosed only by palpation and testicular biopsy. The site and extent of obstruction in the ductal system can only be demonstrated after scrotal and inguinal exploration. Occasionally urethrascopic examination with inspection or calibration of the ejaculatory ducts is indicated.

A large number of operations for the correction of sterility have been described in the literature. In the main, these operations may be divided into four groups: those for (1) union or anastomosis of the vas and the epididymis; (2) anastomosis of the vas with individual epididymal or testicular tubules; (3) anastomosis of the vas deferens to a spermatocele; and (4) re-union of the cut ends of the vasa for reestablishment of luminal integrity. Variations of these procedures are encountered when one vas is anastomosed to the epididymis on the opposite side of the scrotum.

I would like to mention another method I have devised recently that is, up to now, unpublished. If complete occlusion of the distal portions of both vasa precludes any possibility of success by the methods already mentioned, the free and cut ends of the vasa may be brought into midline of the scrotum and then allowed to empty continuously into an inverted skin pouch. The purpose of this procedure is the creation of a reservoir from which material can be obtained for repeated attempts at artificial insemination.

Martin[1] reported a method of laterolateral anastomosis of the vas into the globus major of the epididymis. After this, a number of modifications of this procedure resulted. The persons most directly connected with these are Fuller, Hagner,[2] Quinby,[3] McKenna,[4] Bogolyuboss, and, more recently, Michelson[5] and myself.[6] The technique varied largely in the choice of suture material; some use silk, some horse hair, human hair, silver wire, stainless steel, or nonabsorbable surgical suture. The principles of the operation, in most instances, are the same.

POSTOPERATIVE FOLLOW-UP

Postoperative follow-up observations in this work are often difficult and analysis of the results unsatisfactory. Bayle[7] has recently described a series of 103 operations in which epididymodeferent duct anastomosis was performed in 72 instances. He states that 36 patients had a successful result and that 23 of these brought about pregnancy. Busse[8] followed 13 patients after epididymovas anastomosis and found living spermatozoa in 6. In five of the successful operations a nonabsorbable surgical suture splint was used; without such a splint, there was one successful operation and six failures.

My results in epididymovas anastomosis have not been so encouraging as those mentioned above. Of the 61 patients in whom there was sufficiently hopeful indication for success to warrant the performance of bilateral or unilateral epididymovas anastomosis, in only 23 of these could it be said that a completely satisfactory follow-up was recorded. Fourteen of these 23 had normal appearing spermatozoa in the ejaculate on repeated examinations. Five of these men were said to effect pregnancy. A cross anastomosis was done on five patients, and two of these were successful.

My records suggest that there was reestablishment of exit of spermatozoa after epididymovas anastomosis in about 20% of the patients, but these records further indicate that actual fertility was restored in not more than 10%. It is obvious that follow-up of these patients, even though they are under fairly good control, lacks authenticity and accuracy because of the many aspects of the problem.

In the seven patients in whom inadvertent surgical ligation had been done, three had a completely successful reanastomosis. A proven pregnancy, with a full term healthy child followed in one instance. Two of the patients in whom the operation was unsuccessful were operated on a second time but in neither was the outcome successful.

Prior to 1945, re-union of the vasa was performed in 14 men who had previously been purposely sterilized by bilateral vas resection. In nine of these patients the outcome was successful as evidenced by a careful series of follow-up examinations over a period of from 2 to 15 years. Since 1947, I have seen 24 additional patients who had undergone purposeful bilateral vas ligation or resection. All of these were operated on with the following results.

In eight patients, resection of the vasa had been done so close to the globus minor of the epididymis that satisfactory re-union of actual vasal luminas was not possible. In each of these patients, an attempt was made to unite the proximal, tortuous portion of the epididymis to the vas proper. In two of these patients, sperm were subsequently found in the ejaculate. The material was unsatisfactory in number, shape, and motility of the sperm.

[8] Busse, E.: Reunion of Vas Deferens After Surgical Sterilization, Deutsche Gesundh. **5**: 330, 1950.

One of these patients has become azoospermatic again. Pregnancy did not result from either patient with sperm in the ejaculate.

The remaining 16 patients were found to have a reasonably satisfactory anatomic condition to permit vas re-union. This situation prevailed bilaterally in 12 and unilaterally in four patients. Of this group, 10 patients have had what appears to be a completely successful result. By this is meant that spermatozoa have been repeatedly found in numbers above 20 million per cubic centimeter with apparently normal morphology and motility. In two of the remaining six of this group, sperm were found over a period of six months but, subsequently, disappeared completely from the ejaculate. Both of these patients were operated on a second time, and neither obtained a successful result on second attempt. In the other four patients, no sperm were ever demonstrated in the ejaculate after reanastomosis, even though testicular biopsy and fresh material from the cut end of the vas had shown normal findings at the time of operation. None of these four patients has submitted to a second attempt at surgical correction.

Of the eight patients with blockage after vasostomy only one attained success. This patient has been followed for 27 years. His wife never became pregnant.

Despite the reports of a number of observers as to the frequency with which obstruction of the ejaculatory duct is the cause of sterility, none of the patients studied recently have had this lesion, and those, in whom an unsatisfactory surgical result has been obtained, have all been subjected to special examination using the endoscope designed by Herbst and Merricks for this purpose.

I would like to call attention to the idea of an inverted skin pouch in the scrotum in which the vasa can be placed for continuous drainage. This material has been successfully used in one of the three patients in whom this was done. In another instance, a pregnancy was said to occur, but a miscarriage occurred during the fourth month. This procedure could be utilized in instances in which normal ejaculation is impossible, as in paraplegics or after prostatic resection.

SUMMARY AND CONCLUSIONS

The mechanical causes of sterility in men, as found in a series of 123 patients subjected to surgical exploration, are reviewed. The different procedures that have been used in an attempt to reestablish a satisfactory channel for the passage of sperm have been thoroughly investigated, and the results are analyzed as carefully as possible.

The results of epididymovas anastomosis indicate a restoration of possible fertility in about 20%. Reanastomosis of the vasa, after prior purposeful division, is followed by a high percentage of success, if other complicating factors are not present. The results reported suggest that 70% of these persons have a reestablishment of the lumen.

While the results obtained result in both pessimistic and optimistic opinion, continued and more widespread work along these lines seems warranted in the hope of restoring fertility to more of these patients.

ENDOCRINE ASPECTS OF INFERTILITY IN MEN

Peter M. F. Bishop, M.D., London, England

It is clear that the development of the fertile testicle depends primarily on its ability to respond to stimulation, on the production of gonadotrophic hormones by the pituitary to provide that stimulation, and on the existence of intact neurohumoral pathways from the hypothalamus to ensure that production and liberation of the gonadotrophic hormones take place. The principal endocrine factors in infertility in men are, therefore, likely to be associated with disorders of this hypothalamic-pituitary-gonadal axis.

Whether extra-axial endocrine factors play an important part in the etiology of infertility in men is a matter of some interest, though to my knowledge there is little reliable clinical or experimental evidence concerning the effect of other endocrine glands on the components of the hypothalamic-pituitary-gonadal axis. Diabetes, for instance, is sometimes accompanied by impotence, but is a diabetic man otherwise inclined to be infertile? Meaker in 1934 thought so, but is there any modern evidence to judge from? Women with Addison's disease sometimes become pregnant; are men with Addison's disease infertile? Few studies using urinary follicle-stimulating hormone estimations, testicular biopsy, or analyses of sperm pictures have been carried out on men with Addison's disease, so far as I am aware. Infertile couples are often treated with thyroid extract. Is this treatment empirical? Or do infertile men commonly show signs of hypothyroidism as demonstrated by basal metabolic rate, protein-bound iodine, or radioactive iodine studies? In some experimental animals, such as rabbits, thyroidectomy or administration of antithyroid drugs leads to testicular degeneration, and it is suggested that the induction of a state of thyroid overactivity improves the motility and density of sperms. Is there any evidence that this is so in the human man?

Since infertility in men is our subject, we must confine the discussion to those conditions in which infertility is the presenting complaint. In a man with a suprasellar cyst caused by a craniopharyngioma, the features of the extremely rare condition of Fröhlich's syndrome may be revealed, namely, those classical signs of hypothalamic involvement, obesity, stunting of growth, sexual infantilism, and possibly diabetes insipidus, and he may incidentally be infertile. In a man with Laurence-Moon-Biedl syndrome other congenital abnormalities, such as retinitis pigmentosa or polydactyly, may be revealed in

addition to the hypothalamic tetrad. He also will, incidentally, be infertile. One expects to find those clinical rarities elsewhere than at a fertility clinic. A panhypopituitary dwarf with short, though symmetric, stature, absence of body hair, and lowered basal metabolism will also have immature genitalia and will be infertile. Probably his diminutive size will have caused concern previously, and he is likely to be unmarried. The eunuchoid with primary panhypogonadism may already be receiving substitution therapy in the form of testosterone implants, but the therapy will be to help him achieve manhood rather than parenthood. Even the youth with gynecomastia caused by the Klinefelter syndrome will become embarrassed and concerned about his breast development before it has been discovered that he is infertile. Although there are conditions affecting the hypothalamic-pituitary-gonadal axis that give rise to infertility in men, the conditions that interest us most are those that cause a physically normal and healthy husband to go to a fertility clinic where he is told, to his horrified surprise, that his aspermia or defective spermatogenesis is the reason he and his wife have so far failed to have a child.

TRANSIENT INFERTILITY

Before going any further, we must bear in mind the possibility of transient infertility from which spontaneous recovery may take place without the aid of any specific or endocrine therapy. A good example is the transient infertility that may follow an acute febrile illness. It is difficult to say which component of the axis is affected. Another example is malnutritional sexual failure, such as was experienced by men in Japanese and other prisoner-of-war camps in whom the libido was awakened with the food parcels and in whom gynecomastia often appeared on the troop-ship returning home. The gynecomastia in these men suggests that the component of the hypothalamic-pituitary-gonadal axis affected is the gonad. A third possibility is gonadal failure of hypothalamic origin that may follow an emotional experience or an environmental change such as might correspond to the hypothalamic amenorrhea that often affects women submitted to similar disturbances.

PITUITARY GLAND OR GONAD?

Passing down the axis we come next to the pituitary and to the gonad, and in order to determine the site of the primary lesion we have, to aid us, the estimation of urinary follicle-stimulating hormone. If the cause of the gonadal failure is lack of production and release of gonadotrophin, then minimal quantities of follicle-stimulating hormone will appear in the urine. If the failure is primarily in the gonad, especially in the seminiferous tubule, then the reciprocal control that exists between a pituitary trophic hormone and its target hormone will break down, and uncontrolled production and release of follicle-stimulating hormone will occur and relatively large quantities will appear in the urine. Testicular biopsy alone will not necessarily reveal whether the failure is primarily pituitary or primarily gonadal.

The cases of pituitary failure that are of interest are those of selective hypopituitarism. In some cases both gonadotrophic hormones (follicle-stimulating hormone and interstitial cell-stimulating, or luteinizing, hormone) may have failed. Not only aspermia is found but also eunuchoidism, a condition that Albright has described as eunuchoidism with low follicle-stimulating hormone. In other cases the production and release of interstitial cell-stimulating hormone are normal, the interstitial cells of the testis produce adequate quantities of testosterone, and there is no evidence of androgenic deficiency. Follicle-stimulating hormone production, however, has failed, and the aspermia is due to lack of stimulation of the germinal epithelium. It is clear that if there were available a potent human pituitary gonadotrophin of the follicle-stimulating variety, some of these cases of hypogonadotrophic hypogonadism might be remediable. Work along these lines has already been reported. Furthermore, a recent report from Albright's group in Boston suggests that chorionic gonadotrophin is capable of inducing maturation of all the elements of the testis including the germinal epithelium, with production of numerous active spermatozoa in cases of eunuchoidism with low follicle-stimulating hormone.

If the gonad itself is the primary source of the failure, classification cannot at the moment be very precise or clear-cut for two principal reasons. One is that a considerable number of clinical syndromes have been described, and it is as yet too early to decide whether some of them are minor variations of one fundamental syndrome or whether there are in fact a large number of clearly different syndromes. Though immense progress has been made in the study of the histology and histochemistry of the testis since Dr. Hotchkiss and Dr. Charny introduced testicular biopsy in the diagnosis of sexual disorders in men in the early 1940's, there is still a good deal to be done. The significance of features such as peritubular fibrosis and the glycogen content of the Sertoli cells is as yet not absolutely clear. The second difficulty is that there is still no exact agreement concerning the function of the various structures of the testis. It is universally acknowledged that the interstitial cells produce testosterone, that they are controlled by the interstitial cell-stimulating, or luteinizing, hormone of the pituitary gonadotrophic complex, and that spermatogenesis is a function of the germinal epithelium. But there seems some doubt about the function of the Sertoli cells. A second testicular hormone has been postulated; McCullagh named it "inhibin" over 20 years ago, though it may be more prudent at the present time to refer to it as the x-hormone. It is thought to support spermatogenesis, to inhibit follicle-stimulating hormone production and the mammogenic effect of testosterone, and, possibly, to stimulate interstitial cell-stimulating hormone production. These functions are remarkably similar to those of estrogen in women. It is possible that this hormone may be estrogen. Where is the x-hormone produced? Some, like McCullagh, believe that it is produced by the germinal epithelium; others, like Albright's Boston group and del Castillo and his group at Buenos Aires, say the Sertoli cells; and there is some evidence that the interstitial cells may secrete it. Finally, there are some like Nelson and Heller who find no evidence of the existence of "inhibin." They suggest that the increased follicle-stimulating hormone production in these syndromes of testicular deficiency can be explained by the theory that this hormone is not utilized because of failure of development of the appropriate testicular cells.

GONADAL CAUSES

We proceed to primary gonadal causes of infertility in men. The genetic disorder of testicular agenesis, equivalent to that of ovarian agenesis (Turner's syndrome), is rare in men although cases have been described. A number of congenital abnormalities, such as dwarfism, webbed neck, and coarctation of the aorta, may accompany gonadal deficiency. Panhypogonadism, or eunuchoidism, is due to a failure of the testis during adolescence, perhaps because of uncorrected cryptorchidism or other less well-defined causes that prevent the normal adolescent development of testicular function. The failure may turn out to be irrevocable; it may be due simply to delayed puberty, and adolescence and the entry into normal adulthood may eventually take place in the 20's instead of the teens. It is important to realize this possibility in assessing the claims of specific endocrine therapy. Unless there is some regression when therapy is discontinued, it must be suspected that the condition was a late puberty. Selective hypogonadism refers to those conditions in which failure is confined to one or two but not to all three of the main structures that control testicular function. I have chosen three such syndromes to discuss, though obviously there may be more. The first is the condition of germinal aplasia described recently by Sohval and Soffer. In germinal aplasia there is preservation of the Sertoli and Leydig cells. The second is a condition of testicular dysgenesis described by del Castillo and his group. They regard it as being due to a defect in the development of the testis. There is absence of germinal cells although the tubules are of normal size and entirely composed of Sertoli cells. Interstitial cells are intact. Del Castillo and co-workers observed no gynecomastia, obtained normal urinary follicle-stimulating hormone values, and, therefore, credit the Sertoli cells with the production of x-hormone; this view is shared by the Boston group. McCullagh, Sirridge, and McIntosh, however, found elevated urinary follicle-stimulating hormone values in del Castillo's syndrome and adhere to the view that x-hormone is produced by the germinal epithelium. Finally, in the Klinefelter syndrome (described by Klinefelter, Reifenstein, and Albright) there is tubular hyalinization, peritubular fibrosis, and intact Sertoli and Leydig cells. The condition is associated with high follicle-stimulating hormone values and, in some cases, gynecomastia.

It is beyond the scope of this brief survey to go into detail concerning these numerous syndromes of primary testicular failure. Indeed the problem is still in the stage of study and has not yet achieved the stage of dogmatic teaching.

CONCLUSIONS

Since testicular biopsy and urinary follicle-stimulatting hormone estimation have been at the disposal of those dealing with infertility in men, tremendous strides have been made. Undoubtedly this advance will be consolidated. The histology of the testicle is already more informative than that of the ovary, and histological specimens are easier to obtain. Thus, in the very near future we should be able, in many cases, to explain just why men are infertile, though possibly for some time yet the information may be academic. Therapy, however, still lags behind theories of etiology.

HAS A SOLUTION FOR THE "UNSOLVED FRACTURE" BEEN FOUND?

PROBLEMS AND COMPLICATIONS OF FRACTURES OF FEMORAL NECK

H. R. McCarroll, M.D., St. Louis

In a paper on fractures presented before the American College of Surgeons in 1934, Kellogg Speed used the title "The Unsolved Fracture" for discussion of the intracapsular fracture of the neck of the femur. He stated, "this fracture was chosen for discussion because for more than a century its treatment and the results have been a matter of controversy and inquiry among surgeons, and because, although the results obtained today show improvement, they are not at all comparable to those of other fractures." He advised treatment of this fracture by the Whitman[1] method, which consisted of gentle reduction by traction, inversion, abduction to the degree indicated, and plaster immobilization. He added, however, that a few might prefer the use of early surgery, employing selected methods, in an attempt to minimize the period of immobilization and to avoid feared complications. Speed concluded that treatment of the fracture of the femur was entirely unsatisfactory. In the intervening 19 years many changes have been brought about. It seems reasonable, therefore, that we should pause and attempt to reevaluate this problem to determine whether a solution for this universal problem has been found. This study is based on a series of 203 consecutive cases of femoral neck fractures seen in a single private practice during a 15 year period.

The Whitman[1] method for the treatment of femoral neck fractures has been almost entirely discarded. The young orthopedic surgeon in training today scarcely realizes that this method of treatment represented an important step in the development of our present-day methods and that the method of reduction described by Whitman and later modified by Leadbetter[2] is still in use. Since the most conservative methods of treatment

failed to give satisfactory results, it was only natural that many surgeons turned to operative methods and internal fixation. Campbell states that the use of internal fixation was first reported by Langenbach in 1850. Thomas [3] in 1921, and Martin and King in 1922 reported the use of steel screws. Campbell also states, however, that poor available metals, inadequate roentgenographic control, and inaccurate reduction of the fracture in many instances caused the use of internal fixation to be discarded and delayed for many years. Many types of internal fixation have been used. Ivory and bone pegs, pegs prepared from cow's horn, various types of lag screws, triangular-shaped metal spikes, Lorenzo screws, threaded wires, Moore pins, Knowles pins, combination of Lorenzo screws and plates, and various nail plate combinations have been tried in various clinics. Smith-Petersen [4] developed the three-flanged nail and placed the use of internal fixation on a sound basis. His efforts have popularized this method to the extent that it is almost universally accepted today as the preferred procedure in the early treatment of this fracture.

NEED FOR IMPROVEMENT

In spite of improvement in the methods of treatment for this type of fracture, the results still leave much to be desired. Such a fracture may be seen early, accurately reduced, and adequately fixed, and still the late result may be very poor. This is largely because the blood supply to the femoral head is often completely disrupted by the fracture. As a result, aseptic necrosis and subsequent disintegration of the femoral head may be encountered. The problem of aseptic necrosis in these fractures has long been recognized. Sir Astley Cooper, early in the 19th century, stated that these fractures failed to unite because "the ligamentous sheath and periosteum of the neck of the bone are torn through, the bones are pulled apart, and there is a want of nourishment of the head of the bone." The work of Phemister [6] in recent years has added much to our knowledge of this problem. The incidence of aseptic necrosis is quite high, and, in this series of 203 cases, the problem was encountered in 60 instances among patients followed for one year or more. This represents an incidence of aseptic necrosis of almost 40% among patients followed for one year or more. This percentage of aseptic necrosis is more thoroughly appreciated by the fact that 43 cases were followed for a shorter period of time and 12 patients died within six weeks.

While it may be stated that the incidence of aseptic necrosis in these fractures is very high, the exact figures are undoubtedly misleading. Fifty-seven of these patients were initially treated elsewhere, and it would be impossible to state the exact incidence of aseptic necrosis, unless we knew the total number of patients treated during this same period of time by the group of physicians who furnished the initial therapy. The majority of persons who were later referred to an orthopedic surgeon were those in which some complication had followed the initial treatment. On the other hand, if every patient could be followed for 10 years or longer, the incidence would undoubtedly be even higher. One person in this series showed no evidence of aseptic necrosis until after an elapsed time of over 9 years, and at the end of 13 years showed the typical degenerative changes associated with such a process or resulting from a secondary osteoarthritis. In this series of 203 cases there were 50 instances of nonunion. Many of these occurred in conjunction with aseptic necrosis, but several instances were encountered in which a nonunion persisted even though the femoral head appeared to be viable. At the present time there are no means by which the circulation to the femoral head can be maintained, or restored, in these fractures with assurance that aseptic necrosis can be avoided. This, therefore, continues to represent the major portion of the unsolved problem in this fracture.

Moreira, in a visit to the United States in 1936, demonstrated in various clinics the use of the stud bolt screw. This was similar in some respects to the lag screw, which was described by Henry in 1934,[7] and by Henderson [8] in 1937, but seemed to have the distinct advantage of thinner, deeper threads for purchase and fixation of the head. A series of 15 consecutive fractures were treated by this method in the hope that firm impaction of the head and neck of the femur would serve to restore adequate blood supply to the devitalized head. The difficulties encountered in this operative procedure, however, were so great that the results would still have been no better than with the use of the Smith-Petersen [4] nail, even if the incidence of aseptic necrosis had been completely abolished. In a few instances the head of the femur was actually rotated in the acetabulum as the threaded end of the bolt entered the head. Kirschner wires were drilled into the head at times in an attempt to control the rotation, but this was not entirely successful. In this series of 15 cases, 3 patients died within three weeks, the results were unknown in 3 instances, and only 4 results could be classified as good. Two infections were encountered, and there were five instances of aseptic necrosis and four of nonunion. Because the results were inferior and the operative procedure much more difficult, the use of this method was entirely discarded and the three-flanged Smith-Petersen nail has been used exclusively for early internal fixation in all other cases.

In addition to aseptic necrosis, loss of position at the fracture site also represents a complication that is frequently encountered. Pauwels [9] has described three types of fractures of the neck of the femur, varying with the degree of obliquity of the fracture line. These types are roughly horizontal, oblique, and vertical. The vertical, or third, type obviously represents the one that is most difficult to hold and that tends to shift, even though accurate reduction and internal fixation have been obtained. In some instances an associated subtrochanteric osteotomy is justified at the time of the original operation, in order to change the angle of this fracture line from a vertical to a horizontal position. When an osteotomy of this type is performed, internal fixation by means of a nail plate is required in order to accurately fix the osteotomy site as well as the fracture. Such a procedure will usually prevent displacement of the head, but it does not alter the blood supply to the head of the femur and does not decrease the possibility of aseptic necrosis. Two such operations were performed in this group of 203 cases, and in one an aseptic necrosis was encountered at the end of two years, while the other hip was healed and showed an excellent result at the end of three years.

RECONSTRUCTIVE METHODS

Once an unsatisfactory result has been encountered from aseptic necrosis, displacement of the fragments, or from non union, some type of reconstructive measure is required. The Whitman[1] and Brackett reconstructions probably represent the earliest measures used, but the author has had no experience with these procedures. McMurray,[10] Blount,[11] Leadbetter,[2] and James Dickson[12] have been foremost in advocating some form of subtrochanteric osteotomy to overcome this complication. Such an osteotomy will frequently result in union for the ununited fracture, but it cannot control the progressive degeneration of the head associated with aseptic necrosis. Many of these hips, therefore, are still in entirely unsatisfactory condition after this type of treatment. Twelve of the patients in this series were treated by osteotomy, but not a single result could be considered satisfactory after an elapsed time of three years.

Smith-Petersen[4] has long advocated the use of cup arthroplasty for this problem, and the procedure has afforded stability and improved results in many instances. In some instances the femoral neck is quite short and the trochanter may be transplanted inferiorly to produce an apparent lengthening of the neck. Many times, however, the neck of the femur is almost completely absorbed and the anatomic structures are not satisfactory for the usual type of cup arthroplasty. Colonna,[13] in 1937, described a reconstructive procedure applicable to this problem in which the abductor muscles were detached from the trochanter and the trochanter itself was placed within the acetabulum after the head of the femur was removed. The abductor muscles were then attached to the shaft of the femur below the trochanteric level. This procedure was later modified by the use of a cup made of Vitallium (a cobalt-chromium alloy) on the tip of the trochanter so that a smoother surface would be available for contact with the acetabulum. This procedure results in considerable shortening of the extremity, a position of relative abduction at the hip jont, some knock knee, and a distinct limp in walking. This operation was performed in five instances in this series of cases, but the results could be classified as only fair. Stability of the hip was afforded, but there was marked limitation of motion and some discomfort in all instances. No patient improved to the extent that all outside support could be discarded. A cane or crutch was required in each instance.

The use of bone grafts across the site of the fracture has been recommended and used in some instances for treatment of nonunion and aseptic necrosis. Phemister[6] recommended this procedure highly and stated that revascularization and replacement of the head of the femur could be hastened and insured by the use of adequately placed tibial grafts through the femoral neck and into the femoral head. Five patients with aseptic necrosis of the femoral head were treated by bone grafts in this series of cases. No result could be classified as good. The replacement process of the femoral head required a period of several years. Even then, irregularity of the articular surface developed and some degenerative arthritis of the hip was encountered. Pain persisted in all instances and, in some, was so severe that further reconstructive measures were required. One of the greatest disadvantages of the use of the bone grafts is the fact that protection from weight bearing by means of crutches is required over a period of many months and usually for two years or longer.

The Brackett operation, mentioned previously, consists of placing the stump of the neck of the femur in contact with the slightly hollowed femoral head. This was modified by Moore[14] in 1948 and reported as the cartilage cup arthroplasty. He recommended that most of the bone be removed from the head of the femur so that a cartilage cup through which light could be transmitted was prepared. This cup was then used in exactly the same manner as the Vitallium cup, and in some instances the bone dust that resulted from cleaning out the femoral head was used as a paste between the stump of the neck and the cartilage cup. This procedure was used in six cases in this series, and in no instance could the result be classified as satisfactory after three years. In two instances the cartilage cup completely disintegrated, in one it became displaced and additional reconstructive therapy was required, and in the remaining three cases the result could be classified as fair. In each instance there was definite shortening, limp, limitation of motion, discomfort, and some evidence of degenerative arthritis in the hip joint.

Arthrodesis of the hip has also been advocated as a means of treating the unsatisfactory results or complications encountered in fractures of the femoral neck. An arthrodesis of the hip in persons of this age represents a major surgical procedure in all respects. The period of postoperative plaster fixation required for treatment of this type is of major concern and increases the morbidity and mortality rate considerably. Only one arthrodesis has been attempted in this series, and the result was only fair. The patient never recovered to the extent that she was able to be active and self-supporting and spent the remainder of her life in an infirmary for the aged. Arthrodesis of the hip, therefore, represents such a major surgical undertaking that it should be avoided in older persons, if possible.

PROSTHESIS

In spite of these various recommended reconstructive procedures, the treatment of complications encountered in fractures of the neck of the femur has obviously remained unsatisfactory. So little could be offered in the way of reconstructive surgery that one often wondered whether these patients would do just as well to continue the use of one or two crutches if the primary reduction and internal fixation failed to afford a satisfactory result. This plan of therapy, in fact, was recommended for many patients in this series in whom pain was not a major symptom. More recently, the Judets[15] have reported and recommended the use of a replacement type of prosthesis in which the femoral head is removed and replaced, whether it is the seat of a nonunion or of aseptic necrosis. The prosthesis originally described by Judet has been modified by some surgeons, and the all-metal type is now used quite extensively. In instances in which a satisfactory femoral neck remains, the Judet type of prosthesis can often afford a very satisfactory result. Many cases, however, are encountered in which the femoral neck is largely destroyed or the location and obliquity of the fracture line leave very little femoral neck with which to work. Unless an adequate femoral neck remains, a satisfactory purchase for this prosthesis cannot be obtained. Eicher, Fred Thompson, Austin Moore, McBride, and others have devised intramedullary types of fixation for use of the prosthesis in instances in which the femoral neck has been largely destroyed. The use of the replacement type of prosthesis seems to offer considerable hope for improved results in the treatment of these complications of the fracture of the femoral neck. No one person, however, has had sufficient experience with this procedure for us to state with certainty that permanent satisfactory results can be obtained in the majority of cases. No case in this country has been followed for more than a few years, and it is impossible to state whether a replacement type of prosthesis can be expected to stand the wear and tear of weight bearing over a period of 15 or 20 years. It should also be stated, however, that these fractures occur in an age group in which the average expectancy may not be more than a few years and satisfactory results extending over a shorter period of time would still be acceptable. In this series of 203 cases the Judet type of prosthesis has been used in 9 instances, the Eicher prosthesis in 8 instances, and the Fred Thompson type in 2. Several complications have been encountered. Fracture of the shaft of the femur has been encountered in three instances with the use of the intramedullary type of prosthesis. One intramedullary prosthesis has become dislocated twice in the same patient, and in two instances the tip of the intramedullary stem penetrated the outer cortex of the shaft of the femur. In each instance the prosthesis was reinserted in proper position. One instance of dislocation occurred when the anterior portion of the joint capsule was excised and no attempt was made to reconstruct it. Since that time the joint capsule has been preserved in every instance and resutured in order to maintain some degree of postoperative fixation. Complications have been encountered in the use of the Judet[15] type of prosthesis also. In some instances, the stem was too long or too short, and in others an adequate femoral neck was not present for suitable contact with the head of the prosthesis. In two instances the head of the prosthesis contacted only the superior cortex of the femoral neck and, after one year, there is already some evidence of erosion of the bone structure at this point. While it is still too early to make a definite statement with reference to results, with any type of prosthesis, it is possible that the intramedullary type may eventually prove to be far more satisfactory than the Judet type. Careful study over a period of several years, however, will be required before this question can be answered with certainty.

[14] Moore, J. R.: Cartilaginous-Cup Arthroplasty in Ununited Fractures of Neck of Femur, J. Bone & Joint Surg. **30-A**: 313, 1948.

In spite of the complications that have been encountered in the use of the replacement type of prosthesis, this form of treatment seems to offer far more in the way of reconstructive surgery for complications of femoral neck fractures than has been available in the past. One cannot help but be impressed and encouraged by the patient who has been relieved of pain, afforded stability, given improved motion and function, and who has been able to discard crutches for weight bearing after such a reconstructive measure. Such a result is not uncommon and can often be obtained within a few weeks or a few months after surgery. At present, therefore, the use of some replacement prosthesis probably represents the most suitable reconstructive measure that these patients can be offered and should be utilized by orthopedic surgeons in properly selected cases. This type of reconstructive surgery, of course, does not afford a normal hip. It represents a makeshift proposition at the best and is only acceptable today because we have no means of avoiding the complications of aseptic necrosis and nonunion in these fractures.

COMMENT

In the study of any series of femoral neck fractures today, one cannot avoid the impression that most of the progress in the last few years has been made in the reconstructive field. It would seem from this that orthopedic surgeons have been content to accept the theory that present treatment of these fractures is ideal and that no further investigation is needed in this portion of the problem. Yet, the unsatisfactory results are directly attributable to inadequacy of the initial therapy or to degenerative changes that follow disruption of the normal blood supply to the femoral head. Once any such complication has developed, the restoration of a normal hip is impossible. The new and improved reconstructive measures that have been developed for use in the presence of these complications represent important advances in our knowledge of the problem. This, however, may be comparable to "locking the barn door after the horse has been stolen," and we cannot be wholly satisfied with our treatment of femoral neck fractures until a means has been found to control and prevent these complications. It can be safely stated, therefore, that true and lasting progress can be achieved only by more basic study of the fresh fracture. This should include not only the means of initial treatment and fixation but also additional studies of the basic physiology involved. Unless some means is found to control or restore an adequate blood supply to this involved femoral head, the most frequent complication, aseptic necrosis, cannot be prevented and the percentage of grossly unsatisfactory results will continue to be high.

---

15. Judet, J., and Judet, R.: Use of Artificial Femoral Head of Arthroplasty of Hip Joint, J. Bone & Joint Surg. 32-B: 166, 1950.

CONCLUSIONS

In the 19 years that have elapsed since Kellogg Speed delivered his paper entitled "The Unsolved Fracture," operative treatment and internal fixation for the fresh fracture of the femoral neck has been generally accepted and used. In spite of this change in early treatment, the results in a high percentage of cases are still unsatisfactory because of the high incidence of aseptic necrosis and nonunion. When these complications are encountered, various reconstructive measures are now available. Such measures do not restore a normal hip joint, however, and are acceptable only because the frequent complications cannot presently be prevented. Therefore, in spite of the fact that treatment of this fracture has improved tremendously in the last quarter of a century, we can still not be satisfied that a totally satisfactory means of therapy has been obtained. Until the incidence of aseptic necrosis and nonunion of these fractures can be diminished or abolished, we must still classify the fracture of the neck of the femur as "The Unsolved Fracture."

CLINICAL STUDIES ON VERATRUM ALKALOIDS

4. USE OF PROTOVERATRINE IN TOXEMIA OF PREGNANCY

Edward Meilman, M.D., Boston

The primary disturbance responsible for toxemia of pregnancy remains unknown. The similarity to some of the effects of salt-retaining steroid hormones (edema, hypertension, and albuminuria) has led to speculation concerning the etiological role of these hormones. It has not, however, resulted in a logical preventative or treatment other than the long-practiced restriction of salt. Such a comparison serves to separate two major events in the sequence of toxemia. The first is the excessive retention of water and salt. The second is the development of generalized arteriolar vasospasm, with consequent increased peripheral resistance and elevated arterial pressure. In this connection it is of interest that the administration of cortisone to normal persons [1] potentiates the vasoconstrictor response to physiological amounts of norepinephrine, thus illustrating the mechanism whereby a steroid hormone may cause hypertension. Whatever the primary unknown disturbance, most of the serious symptoms and many of the sequelae of toxemia appear to be the result of the intense arteriolar vasoconstriction and the accompanying hypertension. Arteriolar spasm is usually readily visible in the optic fundus. It can be differentiated from true arteriosclerosis by its disappearance or diminution when the blood pressure is lowered or the toxemia abates. Measurements of cerebral blood flow in eclampsia [2] indicate that there are notable increases in cerebral vascular resistance due to arteriolar constriction.

Many measures to lessen the vasoconstriction and hypertension in toxemia have been advocated. These have included spinal anesthesia [3] and a wide variety of drugs,[4] some of which completely or partially block the autonomic nervous system. With this latter group, hypotension may be achieved at the expense of profound disturbances in circulatory dynamics, such as orthostatic hypotension, compensatory tachycardia,[5] and increased cardiac output.[6]

One of the oldest agents used in the treatment of eclampsia was a crude preparation from the root of Veratrum viride. Despite scattered favorable reports of its use in eclampsia,[7] it fell into disrepute except among the Cincinnati group.[7b] The reasons for its poor reputation are not hard to seek. The characteristic hypotension and bradycardia were attributed to a toxic effect on the heart. The transient oliguria at maximum hypotension was considered to be a toxic effect on the kidneys. Moreover, difficulties in preparing reproducible extracts made nausea and vomiting a frequent accompaniment to therapy, and it was almost impossible to obtain pharmacological data in humans concerning the administration of these agents. These difficulties have been overcome to some extent by recent methods of biological standardization [8] capable of detecting a 20% difference in potency; however, there is a relatively narrow margin, not much greater than the limits of biological standardization, between an effective hypotensive dose and one capable of causing nausea, vomiting, or profound hypotension.[9] More accurate evaluation of potency consequently is desirable.

The availability of crystalline Veratrum esters has made it possible to estimate dosage in terms of weight. Studies using protoveratrine, an alkaloid derived from Veratrum album,* have established the dose-response relations of this drug in hypertension due to varied causes including toxemia.[10] With such data it has become possible to administer protoveratrine with predictable and reproducible results. Moreover, pharmacological and physiological investigations [11] in animals and man have presented data to combat long-standing misconceptions

---

The protoveratrine used in these studies was supplied by Eli Lilly and Company, Indianapolis.

Owing to lack of space, some of the bibliographic references have been omitted from THE JOURNAL and will appear only in the author's reprints.

concerning the Veratrum esters. In the dosage required, the hypotension results from a generalized diminution in arteriolar vasoconstriction without autonomic paralysis and not from any toxic effects on the heart. The bradycardia is due to strong vagal stimulation and can be readily overcome by atropine without, as a rule, affecting the hypotension. The oliguria results from the lowering of arterial blood pressure and is transient.[12] Prolonged administration does not result in water or salt retention.[13] In fact, as will be shown below, it does not interfere with diuresis. Protoveratrine diminishes the increased cerebrovascular resistance as it lowers the blood pressure.[14] Similarly, it causes release of renal vasoconstriction in hypertensive patients with or without renal disease.[11c] Resistance in the peripheral vascular bed also decreases without any concomitant increase in cardiac output.[15] This report concerns the effects noted from the administration of protoveratrine to 10 pregnant women with severe preeclampsia, 6 with eclampsia, and 1 with severe essential hypertension.

USE OF PROTOVERATRINE TO CONTROL TOXEMIA OF PREGNANCY

In many instances toxemia develops so early in pregnancy that the chances of fetal survival with immediate delivery are small. Yet if the fetus remains undelivered, intrauterine death often occurs. The danger of placental separation is a further compelling reason for early delivery. Such patients may, in some instances, be carried for several weeks by the judicious use of protoveratrine, until reasonable maturity of the fetus is reached. We have treated 10 patients with severe preeclampsia. The following two case reports, which are typical, illustrate certain features of such treatment.

REPORT OF CASES

Case 1.—A 28-year-old primipara entered the Beth Israel Hospital on March 3, 1952, approximately eight weeks from term, because of hypertension and albuminuria. One year previously she had received radioactive iodine at another hospital for thyrotoxicosis, and at that time a blood pressure of 212/112 mm. Hg was recorded. On admission she was not in acute distress. Her blood pressure was 174/120. There was extreme narrowing of the entire arteriolar tree in both fundi. The heart and lungs were normal. The uterus was palpable 28 cm. above the symphysis. Fetal heart tones were heard. Pitting edema was present over the sacrum and both legs. Urinalysis revealed 4+ albuminuria, no casts, and up to three red blood cells per high power field. The blood nonprotein nitrogen level was 27 mg. per 100 cc. The total protein level was 6 gm. and the uric acid 5.3 mg. per 100 cc.

During the first hospital day, she received 4 cc. of 50% magnesium sulfate every two to three hours intramuscularly, ammonium chloride, and sedatives. Her blood pressure continued at 180 to 200 mm. Hg systolic and 110 to 120 diastolic. The following day this program was discontinued, and she was treated with a low sodium diet and intermittent injections of protoveratrine totaling 0.7 to 0.8 mg. per day in two or three divided doses subcutaneously. The average blood pressure on the first day of treatment was 160/100, the next 170/110, and the third 150/90. The blood pressure remained at this level or lower, averaging only 120/70 with but one injection of 0.2 mg. on the eighth day. Her urinary albumin level had steadily decreased by the eighth day to 120 mg. in 24 hours. The arterioles in the optic fundi were now completely normal in appearance, the spasm having decreased noticeably after one day of treatment.

The patient's course had been so satisfactory that protoveratrine was omitted. On the 9th and 10th days her blood pressure averaged 150/100, and on the latter day her urinary albumin increased to 489 mg. in 24 hours. On the 11th day when the urinary albuminuria increased suddenly to 4+, it was decided to temporize no further and a 4 lb. 2 oz. (1871 gm.) child was delivered by cesarean section. Both mother and baby did well postoperatively.

Comment.—The prompt control of the blood pressure with protoveratrine is noteworthy in this case, especially since a trial with the usual measures was ineffective. The disappearance of arteriolar spasm was very striking, as was the diminution in urinary albumin. The patient's course was one of steady improvement during treatment with protoveratrine. When the drug was omitted, she was quickly in difficulty once again. Control of the hypertension and thereby possibly some of its complications does not, however, remove or control the underlying disturbance in toxemia, as the following case illustrates.

Case 2.—A 34-year-old woman, gravida 1, was observed in the prenatal clinic. A slowly rising blood pressure was noted to reach 160/100 at 26 weeks of gestation. Her weight was 190 lb. (85.9 kg.), representing a gain of only 10 lb. (4.5 kg.). At 28 weeks, despite a low-salt diet, the blood pressure was 158/96 and the weight still 190 lb., but 3+ albuminuria was present. On admission to the hospital she was asymptomatic. Edema of the hands and face was present. The blood pressure was 160/100. The optic fundi showed slight arteriolar narrowing. The albuminuria was 2+. The hemoglobin level was 13.1 gm. and the red blood cell count 4.28 million. The nonprotein nitrogen level was 25 mg., the total protein level 6.5 gm., with 4.1 gm. of albumin and 2.4 gm. of globulin, and the uric acid level 5.1 mg. per 100 cc.

For the first three days she received routine treatment consisting of salt restriction, bed rest, barbiturates, and injections of magnesium sulfate, but without significant response. On the fourth day injection of 0.33 mg. of protoveratrine subcutaneously twice daily was started. Administration of magnesium sulfate was discontinued. The blood pressure was controlled satisfactorily without any undesirable side-effects for the next four and one-half weeks. At the end of the first week of treatment her nonprotein nitrogen level had risen to 43 mg. and uric acid to 8.0 mg. per 100 cc. Urinary output remained good, but albuminuria (1.3 to 1.5 gm. daily) persisted. At the end of four weeks, the nonprotein nitrogen level was 27 mg. and uric acid 5.4 mg. per 100 cc. Her weight diminished by 9 lb. (4.1 kg.). She remained asymptomatic, and the uterus increased in size commensurate with the elapsed time. On the 35th hospital day (33½ weeks of gestation) for the first time the fetal heart was not heard and four hours later the patient went into labor. After nine hours a stillborn infant weighing 2 lb. 12 oz. (1,247 gm.) was delivered with a double foot breech presentation. A tight knot was present in the cord. The placenta contained many infarcts. Six months later the patient's blood pressure was 130/90 and the urine was free of albumin.

Comment. — This patient had only moderately elevated blood pressure but nonetheless the ease of controlling this aspect of the toxemia is noteworthy. Moreover, it appeared to several observers that fetal growth

did occur during the period of treatment, contrary to the usual experience in such cases. It is apparent, however, that blood pressure control alone does not insure a successful outcome. The death of the fetus may have been due in this instance to the knotted cord, but the possibility that prolonged exposure to the toxemia caused fetal death appears more likely.

EFFECT OF PROTOVERATRINE ON THE PREMONITORY SYMPTOMS OF ECLAMPSIA

In his "Textbook of Obstetrics," Irving [16] states, "The appearance of severe headache, visual disturbances, epigastric pain and oliguria indicates that an eclamptic seizure is impending." These premonitory symptoms are so characteristic that one or more of them was lacking in only 15 out of 2,005 cases of eclampsia.[17] The ill omen of renal suppression has recently been reemphasized.[18] The control of such symptoms with protoveratrine coincident to the lowering of blood pressure would suggest that this agent was useful in preventing imminent convulsions.

Four patients with preeclamptic toxemia exhibited at least two of the premonitory symptoms listed above. In all there was prompt alleviation after administration of protoveratrine. The detailed case reports of two of these patients are illustrative.

CASE 3.—A 29-year-old woman, gravida 3, para 2, was admitted to another hospital (Jan. 17, 1949) six weeks from term because of hypertension and albuminuria. Her first pregnancy ended at term with a stillbirth. The present pregnancy was marked by a total weight gain of 40 lb. (18.1 kg.). She had gained 30 lb. (13.6 kg.) in the previous two months, during which time massive edema of the legs and thighs appeared. The blood pressure had risen slowly during the preceding month to 130-140/90. The urine had been free of albumin until one day before admission, when 4+ albuminuria was noted. On admission she complained of occipital headache, epigastric pain, and nausea.

Physical examination revealed an obese young woman with massive generalized edema. Her blood pressure was 160/100. The size of the uterus appeared somewhat small for the estimated length of gestation. The urine boiled solid with albumin and contained white cells, red cells, and granular casts. During the first hospital day the total urinary output was 150 cc. For the first three days treatment consisted of bed rest, administration of meperidine (Demerol) and barbiturates, low-salt diet, and administration of magnesium sulfate by intramuscular injection and 20% glucose solution intravenously. The urinary output rose to 500 cc. on the second day and 510 cc. on the third day, both considerably below her intake. Vomiting and headache continued but epigastric pain had stopped. On the fourth day the magnesium sulfate, meperidine, and barbiturates were not given (except for pentobarbital at night) and protoveratrine was administered once or twice daily in 0.20 to 0.28 mg. doses subcutaneously. Typical hypotensive effects appeared in about one-half hour, e. g., the blood pressure decreased from 160/100 to 130-140/70-80, then from 150/90 to 120/70 mm. Hg. By the fifth day the urine volume exceeded intake and by the ninth day she had lost 16 lb. (7.3 kg.) in weight. On the evening of the ninth day, about 12 hours after the previous injection of protoveratrine, the blood pressure rose to 180/100 and she began to have occipital headache and scotomas. Protoveratrine (0.28 mg. subcutaneously) was promptly given. The blood pressure fell to 150/84 in 20 minutes, and concomitantly the headache and scotomas disappeared. At this time it became apparent that the patient was in labor, and one hour later, when the blood pressure was 158/86, a cesarean section was done. The baby did well and the mother had an uneventful postpartum course. A few months later she had no albumin in the urine, and her blood pressure was normal.

Comment.—In this case repeated injections of protoveratrine did not interfere with establishment of diuresis. Headache, scotomas, and a rising blood pressure that appeared at the onset of labor were readily controlled with the drug until definitive obstetric measures could be taken.

CASE 4.—A 39-year-old woman, gravida 5, para 4, was admitted to the hospital on Dec. 11, 1950, 12 weeks from term, because of hypertension and albuminuria. For five weeks she had noted increasing swelling of the hands and feet. Three weeks before admission the blood pressure was 150/70. Four days before admission she noted epigastric pain, vomiting, and dark, scanty urine. On the day of admission the blood pressure was 220/120. The epigastric pain continued and became quite severe.

Physical examination revealed generalized edema. The blood pressure was 220/120. There was a small hemorrhage in the right fundus. The uterus was enlarged to the expected size, and the fetal heart was easily heard. There was exquisite tenderness in the epigastrium as well as pain markedly aggravated by deep breathing. The urine was dark, turned solid on boiling, and was loaded with white cells, red cells, and granular casts. The nonprotein nitrogen was 34 mg. per 100 cc. The total protein level was 3.8 gm., with 2.6 gm. of albumin and 1.2 gm. of globulin. The uric acid level was 5.8 mg. per 100 cc.

The epigastric pain was not relieved by an injection of 60 mg. of codeine. However, one-half hour after the first injection of protoveratrine (0.3 mg. subcutaneously), the blood pressure fell to 154/96, the epigastric pain promptly disappeared, and she breathed deeply and with ease. She received subcutaneous injections of protoveratrine two to three times daily in doses of approximately 0.3 mg., with a resulting blood pressure of 160-170/86-100, unaccompanied by nausea. During the next four days the urinary output increased to over 2,000 cc. daily, finally exceeding the intake; the albumin decreased in amount. There were no new hemorrhages in the fundi. On the fifth day, ineffective labor was induced by artificial rupture of the membranes. A leg was pulled down and a 1 lb. weight attached. During labor the blood pressure rose gradually from 160/100 to 220/120. Protoveratrine, 0.35 mg. subcutaneously, caused a fall to 154/94 just before delivery. Nine hours after induction a stillborn fetus was delivered by the breech. The postpartum course was characterized by frequent elevations of blood pressure, which were controlled to some extent by injections of protoveratrine.

Comment.—In this instance, epigastric pain of such severity as to simulate diaphragmatic pleurisy, present for four days and not responding to codeine, was promptly abolished when the blood pressure was lowered with protoveratrine. Despite the presence of marked oliguria, in this case as in case 3, it was possible to lower the blood pressure and still induce a diuresis so that the patient was in the best possible condition for definitive obstetrical treatment. Eight of the 10 patients with severe preeclampsia (Dieckmann's classification) delivered living children. One fetus died in utero (case 2) and one died during delivery (case 4).

TREATMENT OF ECLAMPSIA

I have treated thus far five patients with eclampsia. I have similar information on a sixth treated elsewhere under my direction who had been treated previously with massive doses of penicillin as well as magnesium sulfate. Four of the six patients had postpartum eclampsia. Four patients (two ante partum and two post partum) had convulsions while under treatment with magnesium sulfate. None of the six patients had any further seizures after treatment with protoveratrine was begun. The patient in the following case had had four convulsions before treatment was begun:

Case 5.—A 34-year-old woman, gravida 2, para 2, had apparently had an uneventful course during pregnancy except for repeated emotional trauma until about 10 weeks from term, when she called her family physician because of abdominal pain. He satisfied himself that she was not in labor, but did not measure her blood pressure or examine her urine. Shortly after he left she had the first of four generalized convulsions, each one preceded by severe headache and scotomas. She was admitted to another hospital unconscious and immediately given an intravenous injection of 25% magnesium sulfate (dose unknown). Urine obtained by catheter contained albumin (3 to 4+). The blood pressure varied from 180-230/130-150 mm. Hg. The heart rate was 130 to 140 per minute, and the pulse was thin and weak. She was seen in consultation two hours after admission, at which time she had regained consciousness and was fairly well oriented although she had amnesia for the events preceding her entry to the hospital. There was minimal but definite edema of the face, fingers, and feet. The optic fundi revealed intense arteriolar constriction. The size of the uterus was quite small for the estimated date of gestation. Protoveratrine was administered as indicated in the chart for the first day and one-half. Dilatation of the constricted fundal arterioles was visible promptly when the blood pressure fell. On the third day the patient went into labor spontaneously and delivered a living infant weighing about 1½ to 2 lb. (680 to 907 gm.), which subsequently died. After delivery blood pressure elevations were treated for a week with one or two injections of protoveratrine daily. At the time of discharge the blood pressure was normal, but 1+ albuminuria was still present.

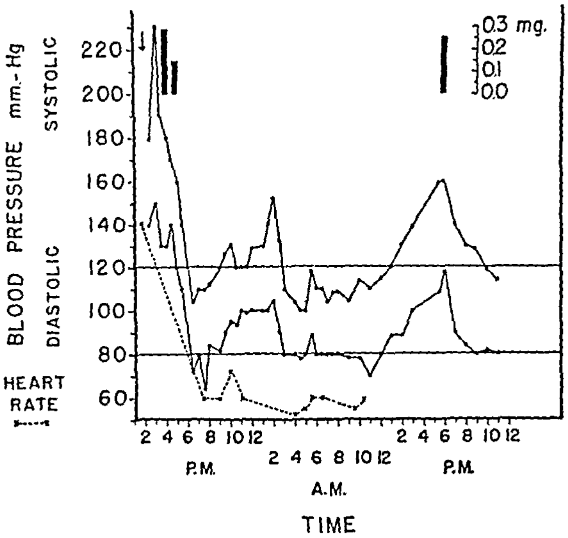
Comment.—In this instance prompt control of the hypertension and convulsions was easily achieved. The long hypotensive action of a single subcutaneous injection of protoveratrine was noteworthy, as well as the ease of administration and calculation of dosage. The initial dose was 4 mcg. per kilogram of body weight; one hour later an additional dose of 2 mcg. per kilogram was given subcutaneously. The following patient had several convulsions, a cesarean section, and anuria before treatment.

Case 6.—A 21-year-old woman, gravida 1, para 1, had gained 12 lb. (5.4 kg.) during the final eight weeks of her pregnancy. One week before term 1 to 2+ albuminuria was detected. A few days before term she began to have abdominal pain and was admitted to another hospital; the blood pressure was 220/140. The following morning she had four convulsions and a cesarean section was performed. The fetus died one hour after delivery. Following operation it was noted that the patient's blood pressure was very low and that she was anuric. She was transferred to the Beth Israel Hospital for management of the anuria.

The patient was lethargic and slightly disoriented. The skin appeared pale and edematous. The blood pressure was 144/110. The fundi showed no hemorrhages or exudate, but there was marked arteriolar spasm. Although the blood pressure was not very high and despite the anuria, she was given protoveratrine subcutaneously. The first injection caused a moderate decrease in blood pressure. By morning the 24 hour urinary output had been only 45 cc. At this time she inadvertently received a dose of protoveratrine that was 66% greater than ordered. Severe hypotension to about 60 to 70 mg. Hg systolic pressure ensued, with a loss of consciousness. The hypotension was treated with 1 mg. of atropine sulfate intravenously and 25 mg. of ephedrine sulfate subcutaneously, which raised the blood pressure to 90/60. After a lapse of about two minutes, consciousness was restored. The blood pressure remained between 90 and 120 mm. Hg systolic for several hours. The fundal arteriolar spasm was much diminished. About one hour later a significant urine flow was noted, and the second 24 hour output reached 300 cc. Intermittent injections of protoveratrine were given to control transient blood pressure elevations. This did not interfere with the marked diuresis that occurred. The nonprotein nitrogen rose to 114, but later fell and was normal at discharge. Recovery was rapid and the patient was discharged with a normal blood pressure and 1+ albuminuria on the 18th hospital day.

Comment.—An overdose of protoveratrine that caused severe hypotension to the point of loss of consciousness did not interfere with, nor did it delay, the appearance of diuresis in this patient with severe renal tubular pathology. Hypotension of this degree from other causes, not involving a generalized vasodilatation, would almost certainly have aggravated seriously the lower nephron nephrosis.

Four of the six patients with eclampsia delivered living children, one of whom died subsequently of prematurity (case 5). One patient was delivered by cesarean section of a live child, which died one hour later, before the patient was transferred to this hospital (case 6). One patient (not described in detail) had had several convulsions and was admitted in coma, at which time the fetal heart could not be heard. After control of the blood pressure with protoveratrine, the patient roused from coma and was delivered from below of a stillborn fetus.



This patient (case 5) had four convulsions before admission to the hospital. The arrow denotes an intravenous injection of 25% magnesium sulfate, following which the blood pressure remained elevated. The heavy vertical bars indicate the subcutaneous administration of protoveratrine. The first dose was 4 mcg. per kilogram, the second was 2 mcg., and the next two each 5 mcg. per kilogram. Vomiting occurred once after the third injection of protoveratrine. No further convulsions ensued.

CONTROL OF SEVERE ESSENTIAL HYPERTENSION

Patients with essential hypertension, especially in the older age group, have a well-known increased incidence of toxemia. In persons of this type, treatment with protoveratrine may be useful in permitting the pregnancy to continue to term or good viability, as in the following case report.

Case 7.—A 41-year-old woman, gravida 2, para 0, was admitted to the hospital during the 27th week of gestation because of hypertension and edema. The family history revealed that her mother and sister had hypertension, the former having died of hypertensive heart disease and the latter of malignant hypertension. The patient had cared for her sister during her final illness, which was complicated by a cortisone psychosis following bilateral adrenalectomy. This period coincided with the early months of her own pregnancy. Following her sister's death, she undertook the additional duties of caring for the latter's children.

For 10 years the patient had labile hypertension for which she had placed herself on a low-salt diet. During the pregnancy a marked decrease in exercise tolerance developed. She climbed stairs only with difficulty and had to sleep on two pillows. There were frequent occipital headaches and occasionally epistaxis. Edema of the legs was noted as early as the third month. Her weight had increased from 212 to 236 lb. (96.3 to 107.2 kg.). The blood pressure was normal early in pregnancy but by the 24th week was 166/90, two weeks later 186/100, and just before admission 236/110 mm. Hg. She had been receiving ammonium chloride since the third month. During the month before admission she had consumed four or five bottles of Alka-seltzer (acetylsalicylic acid, monocalcium phosphate, sodium bicarbonate, and citric acid) because of nausea and abdominal distress.

Physical examination revealed a short, very obese woman, lying on two pillows with slight dyspnea. The temperature was 98 F, the pulse 90, the respiration rate 22, and the blood pressure 220/110 mm. Hg on the right arm and 190/100 on the left. The optic fundi showed one small petechial hemorrhage on the left. The arterioles showed only slight constriction but arteriovenous nicking was present. The heart appeared slightly enlarged to the left. A grade 2 systolic murmur was heard at the apex and to the left of the sternum. The size of the uterus was consistent with six months of gestation. There was massive edema of the legs, thighs, hands, and face.

Laboratory examinations showed no albumin in the urine. Blood nonprotein nitrogen and sugar were normal. The total protein was 5.6 gm. per 100 cc.

She was treated with a low-sodium (200 mg.) diet, ammonium chloride, and intermittent subcutaneous injections of protoveratrine. The blood pressure readings ranged from 200-280/100-140 mm. Hg spontaneously. Protoveratrine caused transient falls to 140-160/70-90. She also received one subcutaneous injection of mercaptomerin (Thiomerin) (0.75 cc.). On the eighth hospital day, having lost 11 lb. (5.0 kg.) in weight, and with the blood pressure stabilized at 150/100, she was discharged home on a program of salt restriction.

She was readmitted two weeks later because of scanty vaginal bleeding, which quickly subsided. The blood pressure was 160/90. She had lost an additional 2 lb. (0.9 kg.) and the urine was free of albumin.

She entered the hospital again five weeks later (approximately one month from term) because of an increase in her edema and the appearance of 1+ albuminuria. The blood pressure range was 240-290/140-170. Generalized marked edema was present. She received intermittent subcutaneous injections of protoveratrine with transient decreases of blood pressure. On the fourth day a cesarean section was performed, and a living child presenting in a floating breech position was delivered. The baby weighed 6 lb. 6 oz. (2,892 gm.). Postoperatively, the blood pressure was lowered intermittently with protoveratrine. At discharge on the 20th hospital day, the blood pressure was 200-210/110-120 and 1+ albuminuria was still present.

Comment.—When this patient, aged 41 and primiparous, had massive edema and severe hypertension before the 28th week, it seemed highly unlikely that any therapy would result in a successful outcome. Nonetheless, conservative treatment, aided by protoveratrine, carried her through a difficult and threatening period so that she could continue gestation to a point where a living, healthy child could be obtained.

COMMENT

The use of hypotensive Veratrum esters such as protoveratrine in toxemia requires careful attention to the dose-response relationships in order to use the drug without causing nausea, vomiting or undue bradycardia. In pregnant patients I have found the subcutaneous route the simplest for good hypotensive effect. The dose range is 4 to 6 μg per kilogram of body weight. If no effect is obtained one hour after an initial dose of 4 μg per kilogram, one-half this dose may then be given. If a moderate but inadequate fall in blood pressure occurs following the initial dose, one-fourth of it may be given in one hour. The effective dose may be repeated at 8 to 12 hour intervals as needed. Smaller doses may be given at shorter intervals. Excessive bradycardia is readily overcome by 0.4 mg. of atropine subcutaneously; up to 1 mg. may be used if necessary. Excessive hypotension can be overcome by a variety of pressor amines, of which I have used ephedrine sulfate (25 mg. subcutaneously). The detailed description of the administration of protoveratrine by continuous intravenous infusion, as well as by the intramuscular, subcutaneous and oral routes for prolonged periods, is presented elsewhere.[19]

Although hypotension from Veratrum alkaloids causes oliguria, it is transient, so that retention of water or salt does not occur. It is readily overcome by osmotic diuretics such as glucose, and even in toxic doses does not interfere with establishment of a spontaneous diuresis. Studies of renal clearances during prolonged hypotension with protoveratrine have indicated that renal vasodilatation occurs.[11c]

The number of cases described here is too few for statistical significance. The sequence of events in some of these patients, however, was so contrary to customary experience as to suggest that protoveratrine was an important factor in therapy. There can be little doubt about its effectiveness in releasing arteriolar constriction. This can be readily observed in the optic fundi when the systemic blood pressure is lowered with protoveratrine. The parallel relief of headache and scotomas has led us to concur in the belief that these symptoms result from cerebral vasospasm. It seems likely also that the epigastric pain in toxemia is, in some unknown way, related to vasospasm, since it, too, is relieved by protoveratrine. The action of this drug, and apparently also of crude and partially purified hypotensive preparations from Veratrum [20] in controlling the premonitory symptoms, the hypertension, and convulsions is very impressive. Control of the vasoconstriction in this disease does not attack the disease at its source, but in this control may lie prevention of many of the serious sequelae.

The use of protoveratrine is not intended to replace certain fundamentals of treatment in toxemia such as bed rest and sodium restriction. It is an adjunct, however, and does offer a means of decreasing arteriolar vasospasm and lowering blood pressure to obviate those symptoms and sequelae of the disease referable to the sustained hypertension. Moreover, it affords the obstetrician a prolonged and safe period before instituting necessary obstetric measures.

SUMMARY

Cases are described that illustrate the usefulness of protoveratrine, a Veratrum alkaloid, for controlling and treating toxemia and eclampsia as well as essential hypertension during pregnancy. They include 10 cases of severe preeclampsia, 6 of eclampsia, and 1 of severe essential hypertension. Prompt control of headache, scotomas, epigastric pain, convulsions, and blood pressure elevations was obtained. I believe that protoveratrine is a distinct addition to the armamentarium of the physician in treating these cases.

CLINICAL NOTES

PAIN CAUSED BY POTASSIUM INTOXICATION IN A PATIENT WITH KIMMELSTIEL-WILSON SYNDROME

William E. S. James, M.D.
Paul E. Wisenbaugh, M.D.
and
Norman P. Shumway, M.D., Cleveland

Hyperkalemia, described frequently in the literature,[1] is characterized by such severe manifestations as generalized muscular weakness and paralysis, electrocardiographic changes representing toxicity to the myocardium,[2] and death.[3] In rare instances, potassium intoxication has caused severe paresthesia.[4] This case report of hyperkalemia in a patient with Kimmelstiel-Wilson syndrome describes an unusual and previously unreported type of pain associated with potassium intoxication. The pain was controlled by administration of glucose and insulin and was easily reproduced by administration of excess potassium. This report also illustrates the possible occurrence of hyperkalemia after excessive administration of orange juice and meat broth in treatment of insulin reactions.

REPORT OF A CASE

History.—A 38-year-old white man was admitted to the Veterans Administration Hospital, Cleveland, on Feb. 27, 1951, with the chief complaint of swelling of the ankles of eight months' duration. During the previous three weeks, he had noted increased swelling of the extremities, puffiness of the face, oliguria, and blurred vision. He was known to have diabetes mellitus, which had been discovered in November, 1935, after development of polydipsia, polyuria, and polyphagia, with a 35 lb. (15.9 kg.) weight loss. At that time, he had started receiving protamine zinc insulin. Three years before the present admission, he had been hospitalized with an acute illness characterized by fainting and vomiting and had remained unconscious or delirious for five days. This was followed by the appearance of ankle edema that lasted three days and subsequently recurred repeatedly. About seven months prior to his admission to the Veterans Administration Hospital, he had begun to notice severe aches and cramping pains in his legs, which usually occurred in the evening while he was at rest. During this interval he had been taking protamine zinc insulin, but on one occasion he could obtain only regular insulin and found that after its administration he no longer experienced pain. From that time, he used regular insulin in the evening and rarely had pain. On occasion, he noted recurrence of swelling of his legs, pain, and oliguria (e. g., he could take a 400 mile trip as a truck driver without voiding). The patient had a history of scarlet fever at the age of six years and on one occasion had been told that he had a heart murmur. There was no family history of diabetes or nephritis.

Physical Findings.—The patient was poorly nourished and chronically ill. His temperature was 98.6 F, pulse rate 90 per minute, and blood pressure 100/75 mm. Hg. He was 67 in. (170.18 cm.) tall and weighed 129 lb. (58.5 kg.). His maximum weight had been 162 lb. (73.5 kg.) in 1934; his average weight was 138 lb. (62.6 kg.). There were small pinpoint aneurysms in the fundi, and there was fluffy exudate principally around the macula lutea. A harsh apical systolic murmur was heard. Massive pitting edema of the lower extremities extended upward to the knees.

Laboratory Findings.—A roentgenogram of the chest was normal. Intravenous pyelograms showed normal intrarenal structures with good excretion of the medium. Repeated urinalyses revealed specific gravities ranging from 1.010 to 1.021, constant proteinuria ranging from 1+ to 4+, and infrequent microscopic hematuria. Hemograms demonstrated an anemia with hemoglobin levels of 9.6 to 10.6 gm. per 100 cc. (Sahli method), red blood cell counts of 3.0 to 3.7 million per cubic millimeter, and hematocrits of 29 to 32%. The total and differential white blood cell counts were within normal limits. Blood chemistry determinations during his hospital course varied as follows: blood urea nitrogen from 20.0 to 65.4 mg. per 100 cc., fasting blood sugar from 56.5 to 89.0 mg. per 100 cc. (while receiving insulin), serum total proteins from 5.9 to 6.8 gm. per 100 cc., serum albumin from 3.8 to 4.2 gm. per 100 cc., serum globulin from 2.1 to 2.6 gm. per 100 cc., serum chloride from 91.9 to 110 mEq. per liter, serum sodium from 125.5 to 131.8 mEq. per liter, serum potassium from 5.1 to 8.5 mEq. per liter, carbon dioxide combining power from 16.0 to 26.8 mEq. per liter, serum creatinine from 2.2 to 3.0 mg. per 100 cc., serum calcium from 8.8 to 10.6 mg. per 100 cc., and inorganic phosphorus from 3.5 to 4.1 mg. per 100 cc. Phenolsulfonphthalein excretion was 6.4% in 15 minutes and 35.4% in two hours, while the blood urea clearance averaged 58.7% of normal. Venous pressure was 80 mm. of saline, and arm to tongue circulation time determined with dehydrocholic acid (Decholin) was 17 seconds. The patient's vital capacity was 4.2 liter (115% of normal).

Hospital Course.—The patient intermittently complained of unusual pain, described as a cramping, gnawing ache in his calves that spread to his upper extremities, hands, and jaws as it became severer. It was accompanied by a peculiar odor and taste that he described as similar to that of acetic acid. In addition, the patient noted extreme weakness while suffering this pain. On one occasion during his hospital course, he had an insulin reaction that was vigorously treated by the administration of orange juice and broth. After this therapy, the insulin reaction was alleviated; nevertheless, the severe pain recurred. It was suspected that the patient was suffering from a profound disturbance in mineral metabolism, since concentrations of ions exert an important, if not controlling, influence on neuromuscular irritability. This relationship has been expressed as follows:[5]

$$\text{Irritability} \propto \frac{Na^{+} + K^{+}}{Ca^{++} + Mg^{++} + H^{+}}$$

Calcium was administered without effect. Since it was suspected that the patient had hyperkalemia, a low potassium diet of 2.5 to 4 gm. of potassium a day was instituted and appeared to benefit him clinically and chemically. Regular insulin also seemed to offer relief, more so than protamine zinc insulin. In order to test any causal relationships between the patient's pain and the hyperkalemia, various studies were performed.

In the first experiment (see table), serum levels of potassium, sodium, carbon dioxide combining power, calcium, and inorganic phosphorus were determined while the patient was fasting, after insulin was withheld, and after insulin was administered. While the patient was fasting and prior to the insulin administration, he had a characteristic episode of pain, weakness, and aberrations of taste and smell. At the same time, the serum potassium level rose from 7 to 8.4 mEq. per liter. Forty-five minutes after insulin injection, the pain had disappeared, and the serum potassium level was 6.5 mEq. per liter. The levels of the other chemistry determinations remained relatively unchanged with the exception of the carbon dioxide combining power, which was lower at each determination.

Three attempts to repeat this experiment in order to demonstrate concurrent electrocardiographic changes were unsuccessful; thus, the second experiment was conceived. In this experiment, the patient was given a solution of 1.14% potassium chloride intravenously after an ordinary breakfast but was not given insulin. He promptly experienced the characteristic pain, which progressed to an alarming degree of severity. Electrocardiograms and serum chemistry determinations were made prior to administration of potassium chloride solution, during the severe pain, and 45 minutes after administration of food and regular insulin. A rise in the level of serum potassium and electrocardiographic T-wave changes consistent with hyperkalemia were observed during the interval of severe pain. After insulin had been administered and coincident with the disappearance of pain, these changes reverted toward normal.

Relationship of Pain to Serum Electrolyte Levels

	Pain	Blood Chemistry Levels: Potassium, mEq./L.	Sodium, mEq./L.	Carbon Dioxide, mEq./L.	Calcium, Mg./100 Cc.	Phosphorus, Mg./100 Cc.
Experiment 1						
Fasting	Absent	6.9	125.8	20.4	8.6	4.9
Insulin withheld	Severe	8.3	129.3	20.6	9.0	4.8
45 min. after injection of insulin	Absent	6.5	130.0	12.9	10.0	4.8
Experiment 2						
Fasting	Beginning	7.0	144.7	22.6	9.6	...
After intravenous administration of 1.14% KCl solution	Severe	8.4	128.0	19.3	9.2	4.0
45 min. after injection of insulin	Absent	6.4	128.6	15.5	9.0	4.0
Experiment 3						
Fasting	Beginning	7.6	131.4	22.3	9.6	4.2
After intravenous administration of 5% glucose in water and insulin	Absent	4.7	132.2	15.1	9.0	2.6

A third experiment was performed to test the effect of suggestion on the pain. A solution of 5% glucose in water that contained the patient's regular dose of insulin was administered. This was falsely and clearly labeled as a solution of 1.14% potassium chloride. The patient thought that the previous experiment was being repeated, but he had no pain. His serum potassium level decreased, and T-waves became lower.

COMMENT

The nephrotic syndrome in Kimmelstiel-Wilson syndrome is characterized by varying degrees of oliguria, azotemia, edema, hypoproteinemia, and hypertension in association with diabetes.[6] At the time of admission, the patient had these symptoms excepting hypertension; however, hypertension appeared 20 months later. Oliguria, azotemia, and acidosis enhanced the potassium intoxication, while insulin and glucose administration decreased the serum potassium level. The mechanism of such decreases in potassium level is not well understood, although it is believed to involve the entrance of potassium into cells either by the specific action of insulin or, more probably, in association with the assimilation and storage of glucose within the cells.[7] Apparently, normal concentrations of intracellular potassium (80 mEq. per kilogram of tissue) and extracellular potassium (4 to 5 mEq. per liter) are necessary for normal neuromuscular function, since abnormal concentrations result in abnormal excitation waves along the nerve fibers.[8] This case report demonstrates the association of hyperkalemia with sensory nerve dysfunction characterized by pain, skeletal muscle abnormalities including weakness, and abnormal electrocardiographic changes. Although parasthesias have been described in association with hyperkalemia, none of the descriptions resemble the pain experienced by this patient.

SUMMARY

A case of unusual pain in a patient with Kimmelstiel-Wilson syndrome associated with potassium intoxication is reported. The pain was alleviated by administration of insulin and glucose. The mechanism of this pain is not well understood nor is the mechanism of lowering serum potassium levels by administration of glucose and insulin. In addition, the report illustrates the possible danger of treating a diabetic patient who has renal disease (e. g., Kimmelstiel-Wilson syndrome) with fluids that are rich in potassium, such as orange juice and broth. The necessity for prompt recognition and early treatment of potassium intoxication in patients with diabetes is emphasized.

HEMORRHAGE DUE TO SELF-MEDICATION WITH BISHYDROXYCOUMARIN

Stuart W. Cosgriff, M.D., New York

Bishydroxycoumarin (Dicumarol) has been a useful agent in the therapy of thromboembolic disease, although, even when carefully controlled, there is an appreciable risk of hemorrhage (4 to 10%) associated with its administration and the subsequent therapeutic hypoprothrombinemia. Obviously, excessive dosage or an unusually sensitive prothrombin mechanism may further increase the risk of bleeding.

This report deals with a patient who was observed and studied and in whom profound hypoprothrombinemia and serious bleeding occurred on two occasions secondary to bishydroxycoumarin administration, apparently self-administered as a manifestation of malingering. The causative role of bishydroxycoumarin was documented by obtaining an elevated value for the plasma level of the drug one month after the last acknowledged dose of the drug.

REPORT OF CASE

A 36-year-old graduate nurse was admitted to Presbyterian Hospital on Dec. 5, 1950, with generalized bleeding of two days' duration. Her history included inactive rheumatoid arthritis; inactive rheumatic heart disease, with mitral insufficiency; an undiagnosed gastrointestinal disorder ultimately classified as functional and characterized by recurrent nausea, vomiting, diarrhea, and abdominal pain in sufficient degree to warrant sedation and narcotic administration; a traumatic right facial paralysis since childhood, repaired by a fascial graft in 1950; two occasions on which it was documented that she intentionally raised the thermometer reading to stimulate an elevation of temperature to 101 and 103 F following the facial nerve plastic operation; recurrent right flank colic, which was allegedly severe enough to warrant the use of morphine for pain relief and about which a urologic investigation revealed nothing abnormal; and her husband's death, in 1949, after a long illness caused by carcinoma of the colon. During an interview with a psychiatrist in 1950 with reference to her diarrhea, the woman was described as an intelligent person who was both evasive and hostile and who exhibited both guilt and hostility toward her husband who had just died. Since his death she had been profoundly depressed.

During the third week of November, 1950, the patient consulted her family physician with complaints of swelling, pain, and tenderness in the right leg of six days' duration. This was diagnosed as phlebitis, and bishydroxycoumarin administration was begun at home; the woman was given a prescription for the drug by her physician. She stated that she took this medication once daily during the next seven days as ordered by her physician in the following dosage schedule: 300, 200, 100, 50, 0, 50, and 50 mg. In this week, her prothrombin time rose steadily from the normal value of 13 seconds to a maximum of 25 seconds. Her family physician stated that the laboratory that performed the prothrombin test had been reliable in the performance of this particular coagulation test.

Three days prior to admission and seven days after beginning anticoagulant therapy, despite a prothrombin time of only 25 seconds, the woman reported oozing from a venipuncture site on the forearm and was instructed by her physician to take no more bishydroxycoumarin. On the subsequent day, gingival and vaginal bleeding appeared; this was followed by several epistaxes and pain in the right flank. On the day of admission, she voided grossly bloody urine. Because of severe flank pain, she received three injections of meperidine (Demerol) hydrochloride. On examination at this hospital, widespread ecchymoses of the skin and gingival and tongue bleeding, as well as flank tenderness, were observed. The urine was grossly bloody.

The pertinent laboratory data were confined to the coagulation mechanism; the whole plasma prothrombin time[1] was reported as greater than 300 seconds (normal 15 ± 1 second) on two tests. The woman was given a total of 150 mg. of vitamin K_1 and 72 mg. of water soluble vitamin K intravenously, with a return of the prothrombin time to 27, 20, and 15 seconds at 6, 18, and 30 hours, respectively, after the antidotal therapy was initiated. Hemorrhagic phenomena subsided satisfactorily. During the first 48 hours in the hospital, she required 12 injections of methadone (5 mg. each) for alleged pain.

On the fifth hospital day (two days after the initial hypoprothrombinemia had been restored to normal), the prothrombin time was found to have increased to 19 seconds and then during the next 48 hours to 26 and 29 seconds. The patient denied having taken any bishydroxycoumarin during the preceding eight days. This was the first instance at this institution in which an apparent rebound hypoprothrombinemia followed vitamin K and vitamin K_1 therapy. On the assumption that large body stores of bishydroxycoumarin might be the mechanism for such a rebound, 100 mg. of vitamin K_1 were given with prompt return of the prothrombin time to 17 seconds and then to 16 seconds on the two subsequent days. She was discharged from the hospital on December 12 without having had any evidence of active bleeding for six days and with the prothrombin time of 16 seconds. She was advised not to take any more bishydroxycoumarin under any circumstances.

On Dec. 29, 1950, the woman was readmitted because of hematuria and low back pain. She stated that since her discharge on December 12, bleeding from the vagina, skin, gums, and bladder had been continuous. She denied having taken any bishydroxycoumarin since December 1, preceding her first admission. The patient was covered with numerous large and small ecchymoses. Evidence of a deep muscular hemorrhage was evident in the right calf. There was exquisite bilateral flank tenderness and pain, with gross hematuria. Because of complaints of severe flank pain, five hypodermics of meperidine hydrochloride and two of sterile saline were given during her first 24 hours in the hospital.

The prothrombin time was 300+ seconds and the Lee-White venous clotting time was 45 minutes. Thirty-six hours after the administration of 144 mg. of menadione sodium bisulfite (Hykinone) and 350 mg. of vitamin K_1, the prothrombin time returned to 16 seconds. The urine cleared of blood, and there were no further evidences of active bleeding. On December 31, 30 days after what the patient stated was the last time she took bishydroxycoumarin, a blood level[2] for bishydroxycoumarin (performed through the courtesy of Dr. Murray Weiner) was found to be significantly elevated (about 10 mg. per liter). She was discharged from the hospital on Jan. 3, 1951.

Eight months later she was readmitted to the urologic service because of flank pain of undetermined cause. She was refused narcotics and was given sterile saline hypodermically, which appeared to control her pain during the five days in the hospital. She reported that no further hemorrhagic phenomena had occurred since her last discharge from the hospital in January, 1951.

COMMENT

In 1951, Stafne and Moe[3] reported on a patient with severe hemorrhage attributable to self-medication with excessive amounts of bishydroxycoumarin. In 1952, Wright and his associates[4] discussed four patients who were considered to be malingerers and in whom there

[3] Stafne, W. A., and Moe, A. E.: Hypoprothrombinemia Due to Dicumarol in Malingerer: Case Report, Ann. Int. Med. **35**: 910, 1951.

[4] Wright, I. S.; Tocantins, L. M.; Olwin, J. H., and Brambel, C. E.: Blood Clotting and Allied Problems, Transactions of the Fifth Conference, New York, Josiah Macy, Jr., Foundation, 1952, p. 77.

had been observed hemorrhagic manifestations due to hypoprothrombinemia secondary to surreptitious ingestion of bishydroxycoumarin. It is of interest that, of the six patients, including the subject of this report, who presented this syndrome, four were graduate nurses and one a physician. Moreover, in each person, there were clinical manifestations of either significant psychiatric aberration or of intent to obtain excessive amounts of narcotics by means of the presenting situations.

The hypoprothrombinemia observed on the first admission of this patient could have represented an unusual sensitivity to bishydroxycoumarin or could have been the result of an error in laboratory technique. The factors in her psychiatric background, however, together with her excessive demands for narcotics raised at the onset some suspicion regarding etiology. When the hypoprothrombinemia returned two days after the prothrombin time had initially been restored to normal, the suspicion of self-medication was strengthened, although undocumented. Such hypoprothrombinemic relapses have been remarked upon by other investigators, although this phenomenon had not previously been observed at this institution. Furthermore, the amount of bishydroxycoumarin that the woman admitted taking was not of massive dosage.

On her second admission the inconsistencies of her history regarding persistent bleeding together with the profound hypoprothrombinemia, despite the alleged absence of bishydroxycoumarin ingestion for 27 days, were too striking to ignore further. This clinical impression of self-medication was confirmed by the prompt return of the prothrombin time to normal after vitamin K therapy and specifically by the finding of the appreciably elevated plasma concentration of bishydroxycoumarin.

In the differential diagnosis of hemorrhagic disorders, it becomes necessary to include the entity of self-induced hypoprothrombinemia. This diagnosis can be established by means of a plasma level determination [5] for the coumarin compound despite denial by a malingerer. Wright [4] reported a case of bishydroxycoumarin self-medication as having been documented by an elevated blood level for the drug.

The fact that bishydroxycoumarin has been reported to be the commonest current cause of fatalities resulting from drugs given orally,[6] an indication of its potential lethal properties, and the availability of such an extremely effective antidote as vitamin K_1 for this type of prothrombin deficiency makes this entity of significant practical importance. Certainly, the possibility of administration of bishydroxycoumarin as a manifestation of malingering or even its administration with criminal intent must be investigated and excluded before a diagnosis of idiopathic hypoprothrombinemia may be safely entertained in any instance of prothrombin deficiency.

SUMMARY AND CONCLUSIONS

A 36-year-old nurse induced a profound prothrombin deficiency and severe bleeding on two occasions by means of excessive self-medication with bishydroxycoumarin (Dicumarol). Despite denials by the patient, the causative role of bishydroxycoumarin in this hemorrhagic diathesis was proved by determining that the woman had a significant blood level for the medicament one month after the last admitted ingestion of it. This self-medication was believed to be a manifestation of malingering, secondary to psychiatric aberrations and a desire for narcotics. The possibility of self-medication with bishydroxycoumarin as a manifestation of malingering or even its administration with criminal intent must be considered and evaluated before a diagnosis of hemorrhagic diathesis caused by idiopathic hypoprothrombinemia can be established.

GASTROINTESTINAL HEMORRHAGE DUE TO RUPTURE OF AORTIC ANEURYSM INTO THE ESOPHAGUS

Daniel G. Calenda, M.D.
and
Joseph F. Uricchio, M.D., Providence, R. I.

Rupture of an aortic aneurysm into the gastrointestinal tract has been encountered twice at the Rhode Island hospital during the past 25 years. In one instance, the duodenum was involved, while in the other there was spontaneous rupture of an aneurysm of the descending aorta into the esophagus. This latter is the subject of our report, because it illustrates that the diagnosis of aorticoesophageal fistula should be considered in a patient with gastrointestinal hemorrhage, when an aneurysm of the thoracic aorta is also present.

REPORT OF A CASE

In September, 1951, a 65-year-old white man was admitted for the sixth time. His chief complaint was hematemesis of 36 hours' duration. He had been admitted to the hospital before because of central nervous system syphilis for which adequate, large doses of penicillin were administered. On admission, the patient was confused and was unable to give a coherent history. The only information obtained was that he was given some medicine to take orally by a local physician. After taking three doses, he began to vomit bright red blood and to pass gross amounts of blood rectally. This occurred several times, and the patient was admitted to the hospital as an emergency case.

The patient was a well-developed, thin, very pale white man. Physical examination revealed that the pupils were constricted and did not react to light. The temperature was 99 F (37.2 C), pulse 84, respirations 20, and blood pressure 90/58 mm. Hg. Lungs were clear to percussion and auscultation. Examination of the heart was not remarkable except for the presence of auricular ectopic beats. The abdomen was soft; it was not tender. No masses or organs could be palpated. Rectal examination was not remarkable.

Laboratory studies showed hemoglobin level, 5.8 gm. per 100 cc.; white blood cells, 12,700 per cubic millimeter; bleeding time, 1.5 minutes; clotting time, 6.5 minutes; prothrombin activity, 80%; sulfobromophthalein (Bromsulphalein) reten-

---

From the departments of medicine and cardiology, Rhode Island Hospital.

tion, 9% in 45 minutes; blood urea nitrogen, 57 mg. per 100 cc.; glucose, 97 mg. per 100 cc.; thymol turbidity, one unit; total protein, 5.8 gm.; albumin, 4.2 gm.; and hematocrit, 22. Reaction to the Hinton test was doubtful. A chest film showed widening of the mediastinum. A calcified placque was present in the aortic knob. The findings were thought to be consistent with an aneurysm of the aorta (fig. 1). A roentgenogram of the chest taken in February, 1950, had revealed a tortuous and sclerotic aorta (fig. 2). An electrocardiogram was normal.

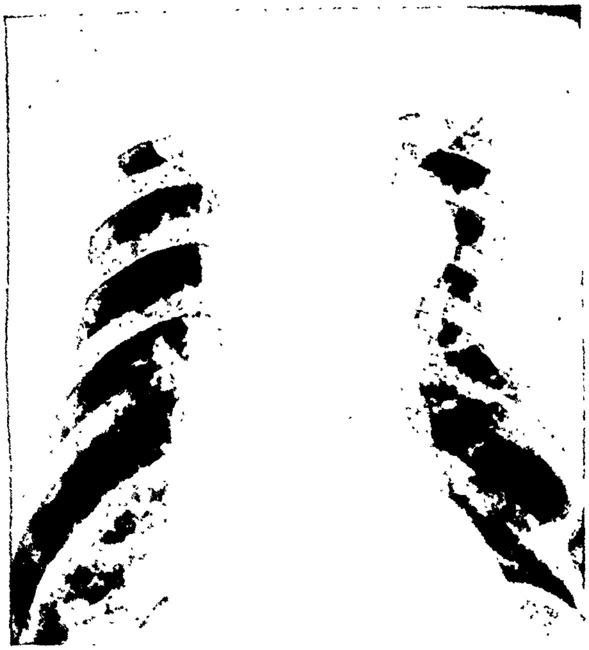

Fig. 1.—Roentgenogram taken in September, 1951, showing considerable increase in the width of the upper mediastinal shadow thought to be consistent with an aneurysm of the aorta.

While in the hospital, the patient was treated with progressive Sippy diet, tincture of belladonna, meperidine (Demerol) hydrochloride, and whole blood. During the second hospital day, he vomited bright red blood on several occasions in amounts varying from 100 to 400 cc. Thereafter hematemesis ceased, the hematocrit stabilized, and the patient appeared somewhat improved. After a total of 6 pints (3 liters) of blood was administered, the hematocrit rose to 30. Seven days after admission, results of a guaiac test were negative for blood in the stool. On the ninth hospital day, there was a sudden episode of hematemesis, and the patient died suddenly. The gross findings at necropsy included saccular aneurysm; descending aortic arch, with rupture into esophagus; gastrointestinal hemorrhage; and syphilitic aortitis.

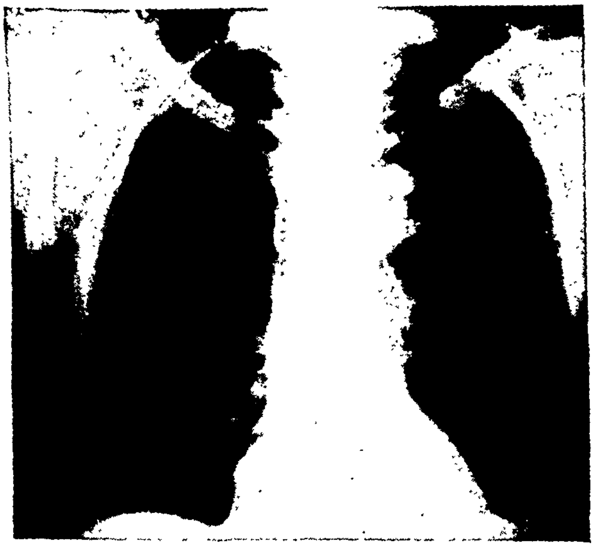

Fig. 2.—Roentgenogram taken in February, 1950, showing tortuous and sclerotic aorta, with slight cardiac enlargement.

COMMENT

Perforation of an aortic aneurysm into the gastrointestinal tract is an extremely rare cause of hematemesis and melena. In 1943, Rottino [1] was able to collect 32 cases. Hunt and Weller,[2] in 1946, added nine more cases and, since that time, others have reported this entity bringing the total up to 55 [3] in 1951. All these resulted from rupture of an abdominal aneurysm into the stomach or small bowel. Gastrointestinal hemorrhage secondary to perforation of a thoracic aneurysm into the esophagus is even more unusual, since in the last 27 years only five such cases have been described in the world literature.[4]

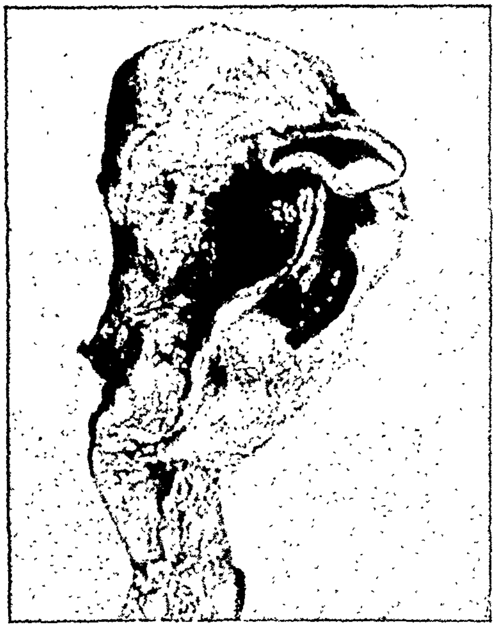

Fig. 3.—Necropsy specimen revealing aortico-esophageal fistula.

SUMMARY AND CONCLUSIONS

A case of spontaneous perforation of a syphilitic aneurysm of the descending aorta into the esophagus, with hematemesis and melena, is presented.

DEATH FOLLOWING THE USE OF EFOCAINE

REPORT OF A CASE

Alden L. Angerer, M.D.
Hung H. Su, M.D.
and
Jerome R. Head, M.D., Chicago

The purpose of this paper is to present the case report of a patient whose death followed intercostal injection of Efocaine. Efocaine is a solution of 1% procaine, 0.25% procaine hydrochloride, and 5% butyl-*p*-aminobenzoate in a solvent composed of 2% polyethylene glycol-300, 78% propylene glycol, and water.

A need has long been felt for a safe local anesthetic agent with a prolonged action. Until recently, Efocaine seemed to meet these requirements, and the drug has been used for many purposes. In proctology these purposes include relief of pain of fissure and fistula in ano, control of posthemorrhoidectomy pain, and relief of pruritus ani; in obstetrics and gynecology for cesarean section, episiotomy, and hysterectomy; in abdominal surgery for hernia, cholecystectomy, and gastrectomy; in dermatology for pruritus; and for prolonged control of pain following various chest operations, trauma to the chest, and pleurisy.[1]

In recent months clinical evidence from case reports seems to indicate that Efocaine has not met one vital pharmacological requirement, i. e., safety. Following its use, there have been reports of perirectal sloughs, unilateral anhidrosis, severe neuralgia persisting for weeks, postinjection neuritis and pain, long-lasting and probably permanent motor paralyses of the lower extremities, and atonic bladders.[2] The following case is the first known in which death is attributed to the use of Efocaine.

REPORT OF CASE

A 55-year-old white man had had bilateral pulmonary tuberculosis since August, 1946. He had been treated by thoracoplasty, paraffin packs, and a rib resection for a complicating empyema. An electrocardiogram taken six months before his last admission indicated normal function. A hemogram at that time revealed no abnormalities. The latest roentgen examination of his chest had revealed an extensive right thoracoplasty and the presence of a large pack in the upper right and the upper left thorax. There was encapsulated fluid in the right pleural cavity.

Since the patient had severe intercostal neuralgia on the right side, an intercostal nerve block with Efocaine was decided upon as the treatment of choice. The procedure was done during an office visit, the patient being entirely ambulatory. The site chosen for injection was the right eighth intercostal space in the posterior axillary line, well away from the spine. A 21 gage, 1½ in. (3.7 cm.) needle was employed, and the procedure was done slowly but without aspirations. During the injection, after approximately 1.5 cc. of Efocaine had been administered, the patient suddenly complained of severe, electric, knife-like pains in his back that radiated down both legs. The patient became extremely pale and collapsed. The legs then became completely paralyzed over a period of not more than several minutes. The pain in the right side of his chest became severer and was associated with shortness of breath. Oxygen therapy was instituted. The patient complained of no nausea, vomiting, headache, or abdominal pain. He was immediately taken to the hospital by ambulance.

Physical examination on admission revealed the pulse to be 124, the blood pressure 110/70 mm. Hg, and the temperature 97 F. There was a flaccid paralysis of both lower extremities, and the deep reflexes in these areas were absent. Sensations were absent below the 10th dorsal level on the right and the first lumbar segment on the left. The bladder was atonic. The sensory and motor reflexes of the upper extremities were intact. The remainder of the physical examination revealed no significant abnormalities except for the presence of an old drainage tube in the wall on the right side of the chest.

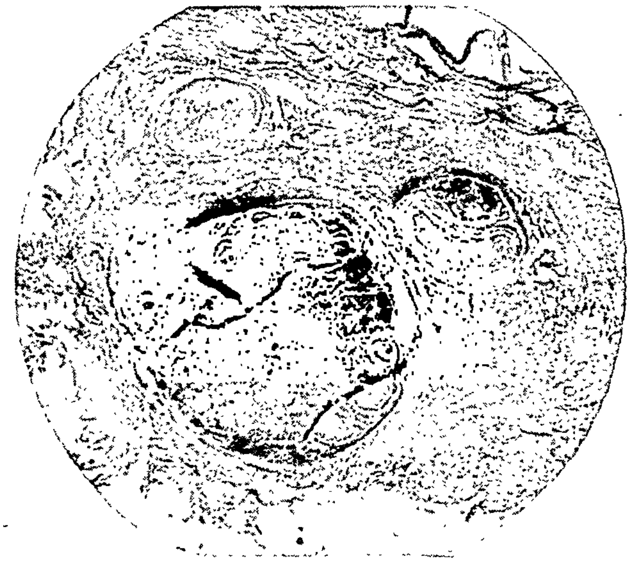

Fig. 1.—Photomicrograph showing dilatation and recent thrombosis of the eighth intercostal vein and thrombosis of the corresponding artery (X 5.3).

The laboratory findings revealed the hemogram and the white blood cell count to be within normal limits. A spinal puncture revealed the initial pressure to be 340 mm. H_2O, with good fluctuation of pressure. The spinal fluid was clear and contained 295 mg. of proteins, 385 mg. of chlorides, and 85 mg. of sugar per 100 cc. No cells were present in the spinal fluid. Roentgenograms of the thoracic spine revealed no significant abnormality except the thoracoplasty on the right and bilateral pleural packs.

On the day following admission, the patient's blood pressure was 170/90 mm. Hg and the pulse was 124. The temperature was 98.8 F. There was sinus arrhythmia and slight cyanosis. The respiration rate was 32, and the respirations were entirely diaphragmatic in nature. The patient complained of numbness in his fingers, but the sensations were intact. On the third hospital day, the respirations were gasping and the pulse and

blood pressure could not be obtained. Artificial respiration was given, the patient was placed in an Emerson respirator, and *l*-arterenol bitartrate was administered intravenously. The patient died on the third hospital day, 44 hours after the onset of his present illness.

At autopsy, the important findings included acute thrombophlebitis of the eighth intercostal vein and recent thrombus in the corresponding artery; focal necrosis and acute inflammation of the spinal cord; petechiae of the pons and medulla; bilateral bronchopneumonia; chronic fibroid pulmonary tuberculosis with cavitation in the upper lobe of the right lung; chronic empyema of the right pleural cavity with pleurocutaneous fistulas; evidence of an old right thoracoplasty with subscapular paraffin pack; and a left extrapleural paraffin pack.

A needle puncture wound was present on the skin of the eighth intercostal space at the posterior axillary line, approximately 8 cm. lateral to the root of the eighth intercostal nerve. The lateral expansion of the subarachnoid space along this nerve was less than 1 cm. in length. The intercostal vein immediately beneath the needle puncture was dilated, acutely inflamed, and filled with a recent thrombus. The accompanying intercostal artery was occluded by a recent thrombus and it was compressed by an extravascular mass composed of red blood cells and inflammatory cells at one side (fig. 1).

The spinal cord was diffusely hyperemic and had three longitudinal, oval-shaped, soft, grayish white, elevated areas on the dorsal aspect of the lower dorsal and lumbar portions. These had maximum measurements of 1.5 by 0.7 cm., 1.7 by 0.7 cm. and 1.8 by 0.7 cm. and were located 1.0, 5.5, and 10 cm. away from the tip of the conus medullaris (fig. 2). Microscopic examination of these lesions disclosed marked hyperemia of the leptomeninges and extensive necrosis and acute inflammation of the spinal cord. The necrosis involved the dorsal funiculi, portions of the lateral funiculi, and the posterior and anterior columns (fig. 3). Focal necrosis associated with slight acute inflammation involving a portion of the dorsal funiculi and the anterior and posterior columns was seen in the sections made through the spinal cord between the lesions. The upper dorsal and the cervical portions of the spinal cord revealed hyperemia of the leptomeninges and of the gray and white matter. Sections of the pons and medulla revealed multiple tiny perivascular hemorrhages and hyperemic leptomeninges.

The immediate cause of death was considered to be respiratory paralysis and/or bronchopneumonia. The petechiae in the pons and medulla are consistent with the clinical course, which included signs of respiratory paralysis.

The spinal fluid was tested for procaine by the methods of Woods and co-workers [4] and of Sanchez.[5] Positive results were obtained by both methods. A semiquantitative estimation of the amount of procaine present indicated an approximate concentration of 50 mg. per 100 cc. Normal spinal fluid gave negative results.

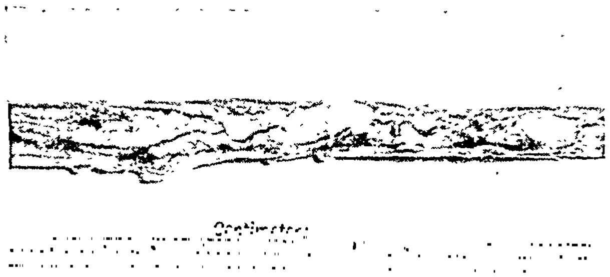

Fig. 2.—Photograph of the spinal cord showing three longitudinal, oval-shaped foci of myelomalacia and engorgement of the blood vessels.

COMMENT

The exact route by which the Efocaine traveled to produce its lethal effect on the spinal cord is somewhat in doubt. Two possible pathways are the intercostal vessels and the perineural sheath.

Factors in favor of the spread by means of the intercostal vessels are (1) the recent thrombus noted in the intercostal vein at autopsy; (2) the rapid development of spinal cord symptoms that began while the Efocaine was being injected; (3) the existence of a venous plexus that is much richer close to the vertebral column [6]; (4) the presence of an anastomosis between the intercostal veins and the internal vertebral plexus through the azygos system and the ascending lumbar veins [6]; and (5) the greater capacity of the veins as compared with that of the perineural sheath.[6]

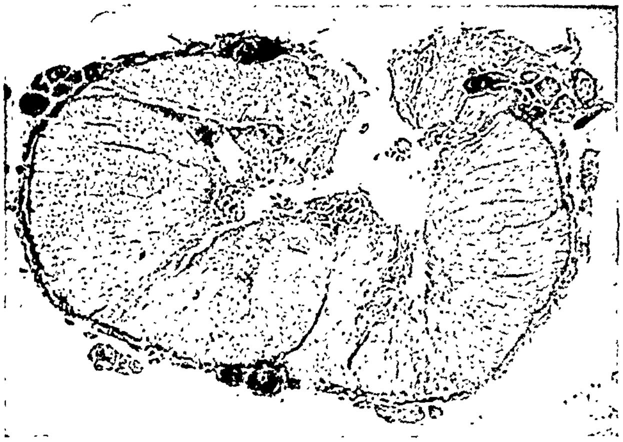

Fig. 3.—Cross-section of the spinal cord through the inferior lesion showing necrosis of dorsal and lateral funiculi and anterior and posterior columns (× 4.5).

Factors in favor of the spread by means of the perineural sheath are (1) no immediate generalized effect was noted in the patient; (2) the fact that the perineural sheath has a direct communication by way of the spinal roots with the spinal cord [6]; and (3) the fact that indigo injected into the sciatic nerve at the sciatic notch can be demonstrated in the subarachnoid space, usually within minutes or hours.[2a] Certainly more experimental investigation needs to be done on the possible pathways of transmission in this area.

SUMMARY AND CONCLUSIONS

In view of the severe complications of transverse myelitis, toxic neuritis, and now death, which have been reported following the use of Efocaine, it is recommended that its use be greatly curtailed and that the drug be used with extreme caution. The case of a patient who died after the intercostal injection of Efocaine is reported. Autopsy disclosed thrombophlebitis of the intercostal vein at the site of the injection and marked necrosis and inflammation of the spinal cord. We believe that Efocaine, since it may produce myelitis and even death, should not be used for local anesthesia, especially in a region near a vital organ such as the spinal cord.

CARCINOMA OF THE CERVICAL ESOPHAGUS AND LARYNX

TREATMENT OF AN ELDERLY PATIENT BY ESOPHAGOLARYNGECTOMY (WOOKEY OPERATION)

Conrad R. Lam, M.D.
and
E. J. Gordon, M.D., Detroit

It is well known that some malignant tumors, especially in elderly persons, grow slowly, and, if they are excised, the prospects for cure are excellent. This case is reported because it illustrates the difficulty in the early diagnosis of lesions that produce dysphagia and the possibilities of cure by operation in carcinoma of the cervical esophagus even after the symptoms have been present for many months and after the larynx has become involved.

REPORT OF A CASE

A 78-year-old white woman was admitted to the Henry Ford Hospital on June 21, 1952. She had noted difficulty in swallowing early in 1950, and roentgenography of the esophagus had been carried out in June of that year (fig. 1*A*); no organic lesion could be seen. The patient was reassured, and during the next year she was able to eat fairly well. Then there was a gradual recurrence of symptoms, and on May 2, 1952, the esophagus was again examined by barium swallow. The report of this examination was as follows: "There is a defect in the barium column involving the upper end of the esophagus which is quite suggestive of new growth. The lesion measured approximately 4 centimeters in length and reduces the esophageal lumen to one centimeter in diameter. The filling defect in the upper esophagus is associated with thickening of the retrotracheal tissues" (fig. 1*B* and 1*C*).

During the three months preceding her admission to the hospital, the dysphagia had become progressively worse, so that only liquids could be swallowed. After the first few days in the hospital, the obstruction became complete and parenteral feeding was necessary. Palpation of the neck revealed some thickening of the structures behind the larynx but no definite fixation. There was one small lymph node palpable in the right anterior cervical triangle, but this was soft and did not suggest malignant invasion. The vocal cords were examined and appeared to be normal. Esophagoscopy by Dr. Donald Bolstad revealed a large ulcerating lesion at the introitus of the esophagus, more prominent on the right. There appeared to be complete obstruction. Tissue that had been removed for biopsy was reported to show squamous cell carcinoma, grade 2.

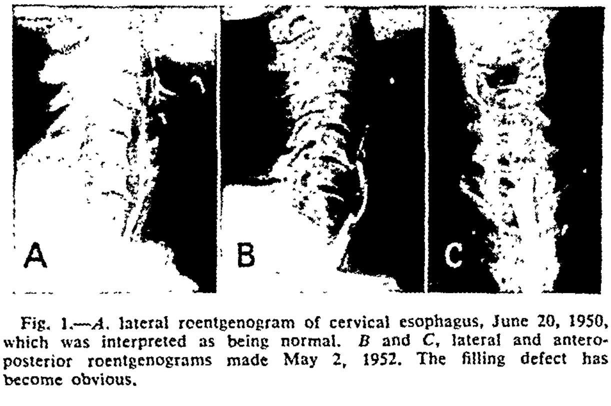

Fig. 1.—*A*, lateral roentgenogram of cervical esophagus, June 20, 1950, which was interpreted as being normal. *B* and *C*, lateral and anteroposterior roentgenograms made May 2, 1952. The filling defect has become obvious.

In 1942, Wookey[1] described a surgical procedure of two stages that made it possible for a patient to breathe and eat after excision of a tumor involving the upper esophagus and larynx. He had operated on four patients whose ages were 50, 62, 52, and 58. The larynx had been removed in only one of these. Two patients were well at the time of the report, with follow-up periods of three years and six months, respectively. Two had died of recurrence after two years and six months, respectively.

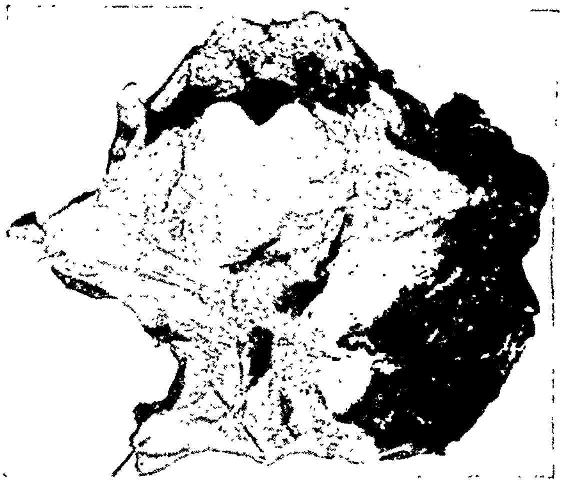

Fig. 2.—Posterior view of excised specimen, with esophagus opened to show the ulcerating carcinoma constricting the lumen. On the right is the right lobe of the thyroid gland and near the top is the opening of the larynx, with the prominent white arytenoid cartilages.

Wookey's operation may be described briefly as follows: At the first stage, a rectangular skin flap, with its base on the right, is reflected from the anterior part of the neck. The left lobe of the thyroid gland is mobilized and removed, unless it is invaded by tumor, in which case it is left attached to the specimen. Tapes are passed around the trachea and esophagus below the tumor and around the hypopharynx above. The trachea is transected just above the suprasternal notch, and an intratracheal tube is inserted for the administration of the anesthetic agent during the rest of the operation. The esophagus is transected below the tumor after traction sutures are placed in the distal end to prevent its retraction into the mediastinum. The tumor mass is separated from the left lobe of the thyroid, unless the latter is involved; the hypopharynx is divided between the hyoid bone and the larynx; and the specimen consisting of the lower hypopharynx, larynx, portions of the trachea and esophagus, and one or both lobes of the thyroid is then removed. Esophageal reconstruction is begun at this stage by connecting the pharynx and distal esophagus with a deep fissure made from the skin flap from the anterior surface of the neck. The remaining raw surface is covered with a split-skin graft. The cervical fissure is closed four weeks later to make a tube, which completes the esophageal continuity. In the interim between the stages, saliva escapes freely from the fissure onto dressings and feeding is accomplished through a tube passed through the nose into the stomach. If the tube irritates the nasal passages, it can be passed directly into the thoracic esophagus through the fissure.

Wookey's operation was offered to our patient, and it was readily accepted. The first stage was carried out without incident on July 12, 1952. The right lobe of the thyroid gland was invaded by tumor, and it was removed with the rest of the mass. The lymph node, which had been palpated before operation, was excised separately. Examination of the specimen showed that the primary tumor and its local extension had been removed, with a fairly adequate margin in all directions (fig. 2).

The pathological report was as follows: "The specimen consists of a larynx upon the posterior surface of which there is a portion of the esophagus which has been opened. The

Because of lack of space, figure 3 has been omitted from THE JOURNAL and will appear in the authors' reprints.

[1] Wookey, H.: The Surgical Treatment of Carcinoma of the Pharynx and Upper Esophagus, Surg., Gynec. & Obst. 75:499, 1942.

mucosa of the upper two centimeters is light gray and pearly in appearance. Below this point there is a very large shallow ulcerated area which measures four centimeters in length and which completely encircles the esophagus. There appears to be only about six millimeters of intact esophageal mucosal margin at the lower end. Sections through several portions of the ulcer show widely infiltrating carcinoma of the squamous type. Numerous epithelial pearls are present. The edges of this growth are adjacent to the normal stratified squamous epithelium of the esophagus and appear to be arising from it. Section of the accompanying lymph node shows no evidence of tumor invasion. Impression: squamous cell carcinoma of the esophagus, grade II." (Dr. F. W. Hartman)

The first stage of the operation was well tolerated by the patient. Tube feedings during the ensuing weeks consisted of homogenized food prepared in a Waring Blendor under the direction of Dr. James Barron. The tracheotomy tube was removed permanently at the end of three weeks. At the second stage, on Aug. 8, the cutaneous fissure was converted into a tube and the outside raw surface was covered by skin from the right lateral portion of the neck. This skin was sutured under considerable tension, with the result that a part of the suture line of the tube was disrupted and two further minor procedures, on Aug. 25 and Sept. 18, were necessary before final closure of the reconstructed esophagus was obtained. The patient was discharged on Sept. 28, at which time she was eating a soft diet.

The patient leads a remarkably normal life at home. She eats at the family table, since she requires no special diet. The tracheostomy is inconspicuous, but she prefers to cover it with a lace dickey (fig. 3). She is able to speak whispered phrases that are audible across the room. No attempt has been made to teach her the more extensive esophageal speech such as many patients who have undergone laryngectomy are able to master. Examination of the neck eight months after the first operative stage revealed no evidence of local recurrence of the tumor.

SUMMARY

A woman of 78 years with a history of difficulty in swallowing over a period of more than two years was found to have carcinoma of the cervical esophagus with involvement of the larynx. Surgical treatment by the method of Wookey (cervical esophagolaryngectomy with cutaneous esophagoplasty and permanent tracheostomy) gave gratifying results. The more frequent and early use of the esophagoscope in the diagnosis of lesions that produce dysphagia is suggested.

Medical Society Problems.—My discussions in individual meetings with physicians during the past year lead me to the conclusion that, in spite of the information issued through our publications and notices, only a minority of our members realize the full extent of the activities of the Rhode Island Medical Society. Where once we met to discuss some single problem of medical education or a major public health proposal as the only item of business at our Council or House of Delegates meeting, we now face a long agenda supplemented with detailed reports touching upon activities in many fields. Thus we find ourselves resolving matters of air and water pollution, disability compensation for off-the-job injuries and illnesses, civilian and military disaster programs, prepayment insurance for surgical and medical care, health education through such programs as diabetes detection, public information through press, radio, and television, nutritional guidance, public assistance services, financial support for medical education, and legislative proposals ranging from licensure in the healing art to the control of fireworks to prevent injuries.—Albert H. Jackvony, The Medical Society and Medical Character, presidential address before the Annual Meeting of the Rhode Island Medical Society, May 6, 1953, *Rhode Island Medical Journal,* June, 1953.

NATURE OF SPONTANEOUS AURICULAR FLUTTER IN MAN

REPORT OF A CASE OBSERVED DIRECTLY DURING CARDIAC SURGERY

Myron Prinzmetal, M.D.
Alfred Goldman, M.D.
Eleanor Gerlach
and
Rexford Kennamer, M.D., Los Angeles

The mechanism of auricular flutter has become a subject of increasing controversy during the past several years. In 1887, McWilliam [1] introduced the term "flutter" to describe an experimentally produced disturbance in the dog's heart and suggested that the arrhythmia consisted of recurrent impulses radiating in all directions from a single ectopic focus. Subsequent investigators [2] developed the concept of "circulating rhythms," which, in 1918, was applied to the fluttering auricles in man and experimental animals by Sir Thomas Lewis.[3] Lewis' classic circus movement theory was not seriously questioned until 1932, when Brams and Katz [4] reported that flutter produced by electric stimulation failed to end after the hypothetical circus pathway was severed. Certain mathematical inconsistencies in Lewis' calculations were noted by Weiner and Rosenblueth in 1946 [5] and by Selfridge [6] in 1948. Scherf's studies of aconitine-produced flutter, during 1948 and 1949, [7] revealed that cooling or clamping of the aconitine focus restored normal sinus rhythm, while interruption of the circus pathway did not produce changes in the flutter electrocardiograms. From 1946 to 1950 in innumerable instances, flutter produced in this laboratory by local application of aconitine or electric stimulation failed to show circus movement; direct observation by means of high speed cinematography and direct lead electrocardiography established the fact that the flutter wave arose at the experimentally produced ectopic focus and spread outward in all available directions simultaneously, as originally supposed by McWilliam.[8] Rosenblueth [9] maintains, on the other hand, that auricular flutter produced by his crush method is entirely compatible with the circus movement theory. A recent

communication from Brown[10] states that circus movement was obtained in instances of experimental flutter initiated by the crush method but not in instances of aconitine-produced flutter. Indeed, a case is described in which one auricle showed a circus movement, while the flutter impulse spread through the opposite auricle in a linear course. Thus, it appears that the mechanism of auricular flutter may vary with conditions of the experiment, particularly with the method of production employed.

These interesting experimental studies must not be allowed to distract attention from the primary problem: What is the nature of spontaneous auricular flutter in man? A definitive answer can be found only through observation of the human auricle by direct methods, such as the cinematographic and surface lead electrocardiographic techniques employed in dogs. Recently, mechanical and electrical activity in the exposed auricles of several patients with auricular fibrillation has been recorded during mitral commissurotomy.[11] Clinical auricular flutter, in contrast to fibrillation, is relatively rare and seldom occurs under conditions that necessitate surgical intervention. The following case provided a rare opportunity to obtain direct evidence of the nature of spontaneous auricular flutter in a patient.

REPORT OF A CASE

A 49-year-old woman was first seen Jan. 11, 1952, with the complaint of severe frontal headache. Four days previously she had had a convulsive seizure, followed by brief loss of consciousness. Weakness of the left extremities and personality changes, with poor memory, were noted after the seizure. She had rheumatic fever during childhood and had had rheumatic heart disease for many years. Periodic examination by a private physician disclosed irregular heart action, but the ventricular rate was slow and there were no signs of cardiac insufficiency. The patient was not receiving digitalis.

Except for slight aphasia, the significant findings were limited to cardiac and neurological abnormalities. Physical examination revealed no demonstrable cardiac enlargement or thrill. A grade 2 rumbling, mid-diastolic murmur was heard at the apex. The pulmonic second sound was accentuated. Cardiac rhythm appeared irregular. The blood pressure was 120 mm. Hg systolic and 80 mm. Hg diastolic. The electrocardiogram showed auricular fibrillation. Roentgenographic and fluoroscopic examination of the chest revealed moderate cardiac enlargement, with dilatation of the left atrium and right ventricle. Neurological findings included weakness of the left arm and leg, hyperactive reflexes, and a positive Babinski sign in the left leg.

A diagnosis of rheumatic heart disease with mitral stenosis, auricular fibrillation, and residual effects of a recent cerebral embolism was made. The patient was hospitalized on Jan. 11. Five days later, conversion from auricular fibrillation to auricular flutter occurred. As the patient was considered an excellent candidate for mitral commissurotomy, this procedure was performed at the Cedars of Lebanon Hospital on Jan. 19, 1952. Limb lead electrocardiograms recorded shortly before, throughout, and after the operation showed typical flutter undulations. High speed color cinematographs of the exposed auricles were made during a brief interval between incision of the pericardium and fracture of the commissure. The mitral valve was described as of the "fish mouth" type. After commissurotomy, the valve admitted two fingers with little regurgitation. The patient was discharged Jan. 30, after an uneventful postoperative course.

Cinematographic Technique.—After limb lead connections had been made, control electrocardiograms were taken and the chest wall was opened. A specially adapted Bell and Howell motion picture camera mounted on a tripod was located 3 ft. to the left of the patient about 2 ft. above the level of the operating table. Two General Electric Photospot lights (RSP2) were placed on each side of the camera and provided adequate illumination of the photographic field, without adversely affecting the temperature of the heart. With the pericardium open, the camera was focused on the exposed surface of the left auricular appendix, and was operated at a speed of 200 frames per second. The pulmonary artery was pushed down, and both auricular appendixes were photographed simultaneously. Auricular flutter, with an auricular rate of 240 beats per minute, and a 4:1 auriculoventricular block was registered in the limb leads while the motion pictures were being made (fig. 1). The entire cinematographic procedure added less than five minutes to total operating time and was harmless to the patient.

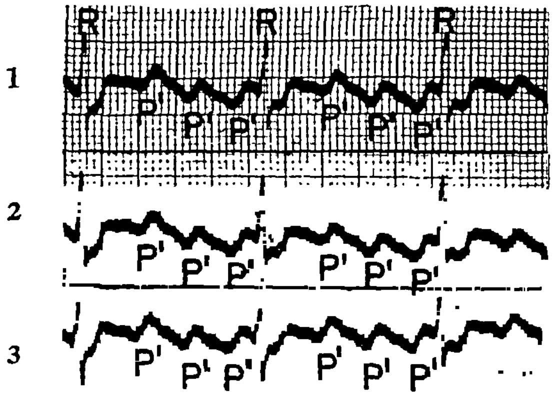

Fig. 1.—Limb leads 1, 2, and 3 recorded simultaneously with high speed cinematographs of the exposed auricles in a patient with auricular flutter during mitral commissurotomy. Note typical undulatory pattern of flutter, composed of inverted depolarization complexes (P' waves) and upright repolarization complexes (Ta waves).

Cinematographic Findings.—The high speed, color cinematographs recorded during the operation provided a clear reproduction of the fluttering auricles in man. When the films were projected at eight frames per second, the motion of the auricles appeared on the screen 24 times slower than it actually was. Such slow speeds show the minutest details of auricular activity with clarity. Successive waves of contraction and relaxation were seen to engulf the left appendix from base to apex. The right appendix began to contract simultaneously with the left appendix. Both appendixes reached maximum systole at the same instant (fig. 2*B*), then began immediately to relax, and finally achieved full diastole simultaneously (fig. 2*A*). In both appendixes, the duration of diastole was about twice as long as that of systole. If a counterclockwise circus movement had been present in the fluttering auricles, the right appendix would have contracted before the left appendix. Conversely, a clockwise circus movement would have involved the left appendix before the right. In the slow-motion pictures, this difference in time of contraction of the two appendixes would have been readily discernible. Simultaneous activation of both auricular appendixes thus is entirely incompatible with the circus movement theory.

COMMENT

The cinematographs described are strikingly similar to films of experimental animals recorded during instances of flutter produced by application of aconitine or

electric stimuli at the caudal end of the auricles.[8] In the dog, as in the patient, both auricular appendixes were seen to contract simultaneously, establishing the fact that no circus movement occurred. Moreover, electrocardiograms taken throughout the operation were similar to those of experimental auricular flutter produced by stimulation of the caudal region; they show inverted depolarization waves followed by upright repolarization waves [8] in leads 1, 2, and AVF (fig. 1). This electrocardiographic pattern is found in the majority of patients with spontaneous auricular flutter. In extensive experimental study in humans and dogs, it has been established that the depolarization wave in leads 1, 2, and AVF is upright when the excitation wave starts at or near the sinoauricular node and is inverted when an ectopic focus exists in the caudal region of the auricles. Thus, the excitation wave of the common type of clinical auricular flutter must arise in the caudal region, from which it travels in a caudocephalic direction and activates both appendixes simultaneously.

Further evidence conflicting with the circus movement theory consists of the frequent presence of an isoelectric interval following the auricular complex in limb and precordial leads of clinical flutter. Of 139 such records analyzed,[8] 95% showed a distinct isoelectric baseline after the Ta wave. Continuous undulations or pure "sine wave" patterns generally appeared only when the auricular rate was exceptionally rapid or when the patient had received quinidine or other drugs. In several instances, an isoelectric interval was present before treatment but disappeared after quinidine was given. If the mechanism of flutter were a self-perpetuating circus movement, excitation presumably would be a continuous process, with no isoelectric pause between auricular contractions. The isoelectric interval must indicate that auricular diastole occurs between successive contractions, as observed in the cinematographs. This observation is incompatible with a reentry phenomenon, but it is readily explained by the theory that flutter originates from a rapidly discharging ectopic focus.

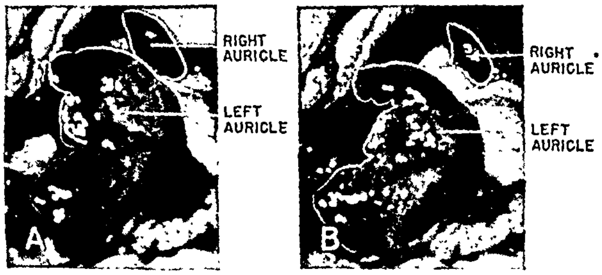

Fig. 2.—Stills from high speed cinematographs showing left and right auricular appendixes in a patient with spontaneous auricular flutter: *A*, both appendixes in maximum diastole at the same instant; *B*, both appendixes in maximum systole at the same instant.

The preceding observations are confirmed by means of esophageal lead electrocardiography. Several workers, including us, have independently reported the configuration of simultaneous esophageal leads from high, low, and midauricular levels in patients with spontaneous flutter.[12] These tracings lead inevitably to one conclusion: In the common type of flutter, the impulse travels from a caudal focus until it reaches the cephalic extremity of the auricles, where it terminates. In the rare type of flutter, the impulse arises in the cephalic region, travels in a cephalocaudal direction, and terminates at the caudal end. The departure of the flutter wave from the focus and its arrival at the opposite end of the auricles is clearly manifested in the esophageal electrocardiograms. In no instance, however, do the tracings yield evidence that the flutter wave leaves the distal extremity and returns to its site of origin, as supposed by proponents of the circus movement theory. If a circus movement was present in the patients studied, it must be assumed that basic electrocardiographic concepts are not applicable to auricular muscle. Such an assumption is contrary to overwhelming evidence advanced during the half century since the invention of the electrocardiograph.

SUMMARY

High speed, color cinematographs of the exposed auricles in a patient with auricular flutter were recorded simultaneously with limb lead electrocardiograms during mitral commissurotomy. The cinematographs clearly showed that the left and right auricular appendixes contracted simultaneously. This observation is entirely incompatible with the circus movement theory. Limb leads 1, 2, and AVF, recorded during the operation, showed inverted depolarization waves followed by upright repolarization waves. Such abnormal complexes occur when the ectopic focus is in the caudal region of the auricles distant from the sinoauricular node. The common type of clinical auricular flutter arises from an ectopic focus in the caudal region, while the rare type arises from a cephalic focus. In all instances, the flutter wave travels away from the ectopic focus until it terminates at the opposite extremity. No circus movement occurs in the spontaneously fluttering auricles of man.

Daniel Drake.—The year 1952 marks the centennial of the death of Daniel Drake. A century ago he was the foremost physician west of the Allegheny Mountains and had an international reputation. . . . Only some of the outstanding firsts can be mentioned at this time. He was the first medical student in Cincinnati, the first to receive a medical diploma and the first to submit to vaccination here. He wrote the first book with a medical section published west of the Alleghenies. This book contained the first comprehensive account of a western town (Cincinnati), the first listing of its indigenous plant life and the first mention of a hitherto unknown local malady, milk sickness. Daniel Drake was a member of the first active faculty (1817) of the first medical institution (Transylvania University) west of the Allegheny Mountains. . . . The hospital which he founded—the Commercial Hospital and Lunatic Asylum of Ohio—for teaching and staffed exclusively by the professors of his medical college was the first in the United States established primarily for teaching purposes. The medical college set up by Drake, now the University of Cincinnati School of Medicine, was the second in the West. It is wholly in keeping with the versatility of Drake's genius that he was also the first to plan for the publication of a medical journal in the West.—E. F. Horine, Daniel Drake and the Origin of Medical Journalism West of the Allegheny Mountains, *Bulletin of the History of Medicine*, May-June, 1953.

CHROMOBLASTOMYCOSIS

THIRTEENTH REPORTED CASE IN THE UNITED STATES

N. C. Barwasser, M.D., Moline, Ill.

In 1943 Moore, Cooper, and Weiss[1] reported two cases of chromoblastomycosis and noted that six cases of the disease contracted in the United States had been reported previously. The 9th case was reported by Binford, Hess, and Emmons[2] and the 10th by Mundt and Moore.[3] Lewis and his associates[4] reported on a 67-year-old man with chromoblastomycosis of seven years' duration on the right hand. Chronic infectious granuloma developed after the hand was injured by wood splinters, and microscopic examination revealed chromoblastomycosis. Conway and Berkeley[5] reported the case of a 44-year-old Negro man who sustained an abrasion on the side of the foot that developed into a slightly elevated tumor with purplish-black nodules. The first case report from Canada was by Berger, Beaudry, and Gaumond.[6] The disease has been reported once each in Massachusetts, Pennsylvania, North Carolina, Georgia, Florida, Texas, and Louisiana, twice in New York, and three times in Missouri. This is the 13th reported case, in which the infection was contracted in either Missouri or Illinois.

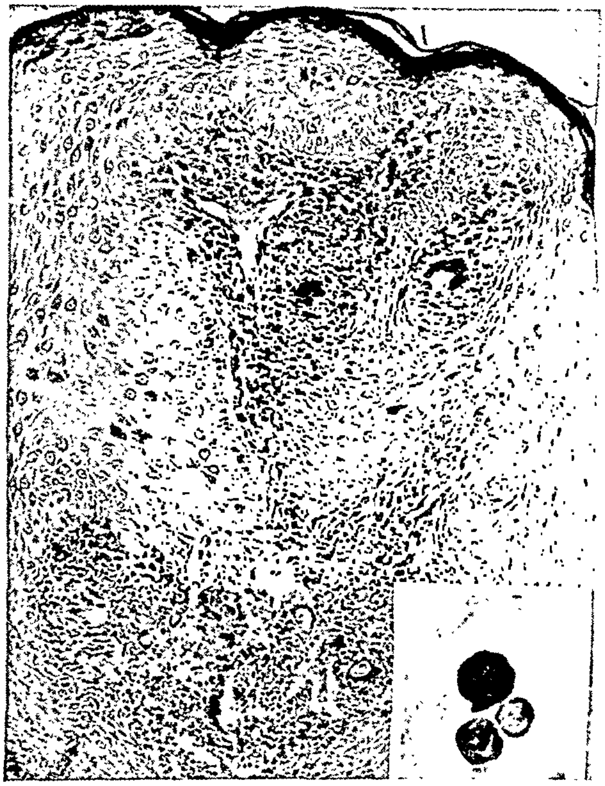
REPORT OF A CASE

A white man, aged 67, had three elevated, dry, verrucous plaques, each about 3 cm. in diameter, on the dorsal aspect of the left wrist. In 1945, while working in Missouri, he had burned his left wrist, at the site of the lesions, with coals from a creosote-dipped railroad tie. Shortly afterward, the patient entered a mental hospital in Illinois; thus the time when the cutaneous lesions appeared was unknown, but they had been evident for two years.

Microscopic examination of the lesion revealed the epidermis to be acanthotic, with a few intraepidermal abscesses containing polymorphonuclear leukocytes and a few eosinophilic leukocytes. In the papillae and dermis there was an abundant infiltrate consisting of many giant cells, histiocytes, plasma cells, lymphocytes, eosinophilic leukocytes, and fibroblasts. Within the giant cells and occasionally, free in the intraepidermal abscesses, were dark brown cells, at times isolated but for the most part in cohesive groups. The diagnosis was chromoblastomycosis. Electrocoagulation performed one year ago apparently destroyed the lesions.

COMMENT

The case report illustrates two possible etiological factors, a burn and exposure to wood. The rarity of the disease in the United States is illustrated by Carrion's[7] report that, of 159 cases reported up to 1947, only 9 were from the United States. The disorder is commonest in Brazil, Cuba, and Puerto Rico. Most authors have stated, however, that the condition is not as rare as it appears to be. After Saxton, Hatcher, and Derrick[8] reported the first two cases in Australia, Tod-Stevens[9] found reports of 33 men and 3 women with chromoblastomycosis in a clinic in North Queensland. Since in almost every case diagnosis is made microscopically, it is obvious that biopsy should be performed on all chronic granulomas.



Granuloma showing many giant cells (hematoxylin and eosin stain, × 113). Inset shows group of three cells free in the infiltrate (hematoxylin and eosin stain, × 731).

Patterns of Gastric and Duodenal Pain.—As a rule, the pain of peptic ulcer is situated in the midline, regardless of whether the ulcer is in the stomach or in the duodenum. Its characteristics are so familiar to physicians that the pain is commonly spoken of as "typical ulcer pain." It is usually situated somewhere between the retroxiphoid area and the umbilicus. If it is of duodenal origin, it may be slightly to the right of the midline; if it is of gastric origin, it may be slightly to the left of the midline. Complications can usually be detected when this pain shifts to other places. Penetration and perforation are commonly manifested by this shift before they can be detected by roentgenographic examination. In general, a shift of pain cephalad is indicative of a higher lesion than is a caudad shift of pain.—L. A. Smith, M.D., Pain Patterns in Diseases of the Upper Part of the Abdomen, *Proceedings of the Staff Meetings of the Mayo Clinic,* July 29, 1953.

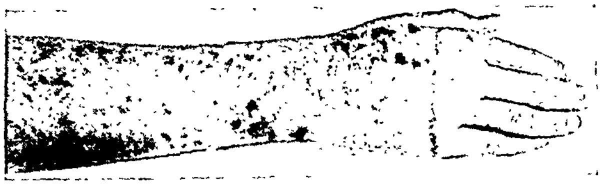
ALLERGIC CONTACT DERMATITIS CAUSED BY MELMAC ORTHOPEDIC COMPOSITION

Adolph H. Conrad Jr., M.D.
and
Lee T. Ford, M.D., St. Louis

We recently encountered two patients who had allergic skin reactions to Melmac Orthopedic Composition. This preparation consists of two powders, a melamine resin (Melmac 405) and ammonium chloride, which acts as a catalyst. For preparation of the plaster bandages, 300 gm. of Melmac 405 is dissolved in 1,000 cc. of water, and just before the plaster bandages are immersed in the solution 30 gm. of ammonium chloride is added. When the plaster is treated with this solution it becomes waterproof and urineproof and appears to be more than twice as strong as plaster of paris; therefore, only about one-half the usual amount of plaster bandage is required, and the cast produced is lighter and smaller than the ordinary plaster bandage.

REPORT OF CASES

CASE 1.—A 13-year-old white boy was first seen by one of us (L. T. F.) on Sept. 22, 1952, because of an injury to the right wrist that had occurred earlier that day. A roentgenogram revealed a linear fracture of the carpal navicular bone. A light Melmac cast was applied, and, when the patient was examined two days later, the cast was found to be satisfactory and the circulation good. On Oct. 2, 1952, the patient began to complain of discomfort under the cast. Examination at that time revealed no fault in the cast, and a roentgenogram showed no change. The patient was seen again on Oct. 6, 1952, when he complained of severe pain under the cast and said that two days previously, weeping had begun. At examination serum was found to be dripping from both ends of the cast. Removal of the cast revealed a severe dermatitis (see the figure). The patient was admitted to the St. Louis Children's Hospital for treatment. At the time of admission, examination revealed a severe vesiculopustular eruption over the entire area that had been covered by the cast. Stockinet had been used under the plaster, and it was probably because of this that the reaction was delayed until the 12th day. It was learned at that time that the boy was allergic to wool also. On the next day, Oct. 7, 1952, a mild, pruritic, erythematous, vesiculopapular eruption appeared on the chest, abdomen, and legs. With treatment with an antihistaminic drug and local applications, the dermatitis subsided considerably, and the patient was discharged from the hospital on Oct. 10, 1952. He was followed as an outpatient, and by Nov. 14 the rash had cleared completely, except for some erythematous patches on the arm at the sites of the previous dermatitis. On Jan. 10, 1953, a patch test was applied with a small piece of the plaster; when removed 48 hours later, a positive reaction exactly like the original dermatitis was present.



Arm of patient in case 1, showing severe allergic dermatitis due to Melmac.

CASE 2.—A 6-year-old white boy has fragilitas ossium. He has had 28 fractures since the age of two years, all except one of which have involved the lower extremities. In June, 1952, he was admitted to the St. Louis Children's Hospital, and Rust intramedullary pins were placed in each femur and each tibia in an attempt to lessen the incidence of fractures. After this procedure, the boy was placed in a double spica cast, ordinary orthopedic plaster bandages being used, and he remained in the cast for two months. Some relaxation of the ligaments in the knees had occurred while he was in the cast, and this along with the atrophy of the bone structure that was present made ambulation difficult. To encourage ambulation and to protect the legs, long leg casts of Melmac plaster bandages were applied on Oct. 24, 1952. No stockinet was used beneath the plaster. On Oct. 31 the child complained of itching beneath the casts, which was severe enough to prevent sleep. A sedative was given but did not control the symptoms. Therefore, on Nov. 1 both casts were removed. Examination revealed a diffuse, moderate erythema of the skin, and at pressure points there was some evidence of early urticarial lesions. The casts were left off, and local applications were given. After one week, the dermatitis disappeared.

On March 16, 1953, patches of Melmac 405, a 3% solution of ammonium chloride, and a piece of the Melmac-treated plaster were applied. On March 18 the patches were removed, and a positive reaction similar to the original dermatitis was found at the sites tested with Melmac 405 and Melmac plaster. These reactions were less severe than those seen in the other patient, as would be expected, since the first patient had had a severer reaction originally.

SUMMARY AND CONCLUSIONS

Two cases of the occurrence of dermatitis under Melmac plaster casts are reported. Results of patch tests with Melmac were positive in each case. Both patients recovered without serious incident.

It is our opinion that the occurrence of two cases of dermatitis due to Melmac plaster is not a contraindication to its use. The advantages offered outweigh the disadvantage of a possible reaction. We suggest that patients be advised of the early signs of such reaction, and that, should these be detected, the cast be opened for examination of the skin.

ADDENDUM

Since this article was submitted for publication, we have observed severe reactions in two additional cases.

SURGICAL TREATMENT OF PERFORATED DUODENAL ULCER IN THE NEWBORN

REPORT OF A CASE

Manuel E. Lichtenstein, M.D.,
Lars E. Lundgoot, M.D.,
Anthony J. Nicosia, M.D.,
and
Lawrence G. Khedroo, M.D., Chicago

Perforation of a gastric or duodenal ulcer and rupture of the stomach or duodenum due to trauma, a defect in the wall of the viscus, or any other cause occur infrequently in the newborn and are clinically indistinguishable from one another. They are usually fatal because of peritonitis, shock, and difficulties encountered in maintaining adequate nutrition and hydration. A suspicion that there may be leakage from the stomach or duodenum

---

From the departments of surgery and pediatrics, St. Elizabeth's Hospital, and Northwestern University Medical School.

into the peritoneal cavity is, therefore, of importance in establishing an early diagnosis and promptly instituting appropriate treatment. The reward in the few instances in which this was done has been the survival of the patient.

It is not always possible to recognize perforation of the gastrointestinal tract in the newborn by physical examination. Roentgenographic demonstration of a pneumoperitoneum was, however, the most important diagnostic aid in the treatment of patients who survived early surgery for closure of a leaking viscus. It was the basis for recognition of the condition in our patient and made possible early surgery with survival of the patient (fig. 1).

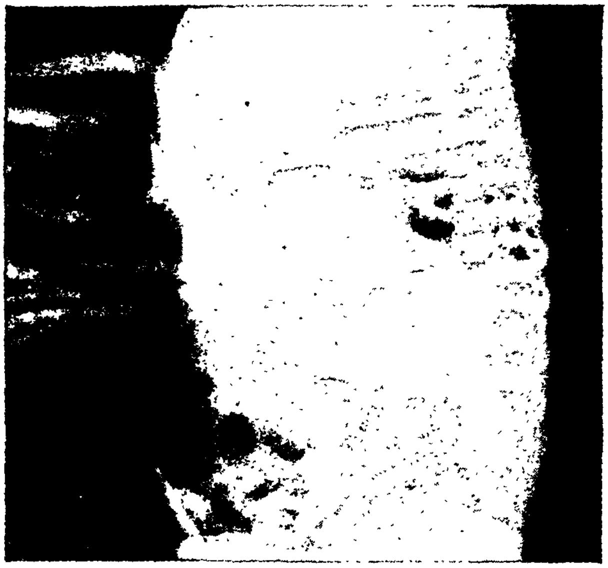

Fig. 1.—Roentgenogram of 3-day-old infant showing pneumoperitoneum.

REPORT OF A CASE

A 24-year-old woman, para 0 and gravida 1, was admitted to an obstetric service on March 15, 1951. At 1:30 p. m. on the same day, she delivered a normal appearing female infant weighing 6 lb. 14.5 oz. (3,120 gm.). The day after birth, the infant passed a small meconium stool, would not take the formula, and vomited several times. Her temperature rose 0.8 of a degree, and she had lost 3 oz. (85.05 gm.). The next day, the temperature reached 98 F, and vomiting continued. On March 18, 1951, the infant was transferred to the pediatric department. Her temperature was 99 F; she was vomiting bile stained material; she was pallid; and the abdomen was distended. Bowel sounds were absent. The baby was given a transfusion of 5 cc. of whole blood and 300 cc. of fluids subcutaneously. A roentgenogram of the abdomen showed a very large amount of free air in the abdomen that shifted when the patient's position was changed. The hemoglobin level was 108.9% (16.6 gm., Haden-Hausser), red blood cells, 4,900,000 white blood cells, 8,450 per cubic millimeter, with 50 segmented cells, 50 lymphocytes, and 4 to 5 nucleated red blood cells per 100 white blood cells.

On March 19, 1951, decompression of the stomach was achieved by suction through a Levin tube. Laparotomy was done through a right rectus incision (paramedian). Free air and clear fluid were noted in the greater peritoneal cavity. In the right subhepatic space, there were bile stained fluid and a thick exudate that flowed from the foramen of Winslow. The lesser peritoneal cavity was explored through an opening in the gastrocolic ligament. On the posterior aspect of the first portion of the duodenum within 5 mm. of the duodenopancreatic angle, there was a 2 mm. opening through which bile stained duodenal contents flowed. Three 0000 silk sutures were used to close the defect (fig. 2). During the postoperative period, the patient was given 50 cc. of whole blood, 250 cc. of 5% dextrose in saline with hyaluronidase (Alidase), and 200,000 units of penicillin. Gastric decompression was continued.

On the day after surgery, the temperature was 101 F; distention was decreased; and no bowel sounds were heard. Dyspnea and slight cyanosis were overcome with oxygen (3 liters per minute) administered through a mask. There was a small meconium stool, and 200 cc. of urine were excreted in 25 hours. During the next two days, the temperature rose to a maximum of 104.8 F; intravenous feedings consisted of 5% dextrose in Ringer's solution; and whole blood transfusions were given. On March 22, 1952, when the temperature was 104.8 F, oxygen was given by mask. Penicillin was administered, and gastric suction was discontinued. On March 23, 1951, the temperature was 103.6 F. Ringer's solution with dextrose was given orally in amounts of 2 oz. every three hours. The decompression tube was removed because of dyspnea, regurgitation, and transient cyanosis. By March 24, the temperature was 100.8 F; oral feedings were continued and retained; and there were frequent golden-yellow stools. The incision was draining serum. After March 27, the temperature never went above 99 F or below 98 F during the rest of the infant's hospital stay. Water and formula were taken well every three hours. On March 28, the weight was 6 lb. 9 oz. (2,976.7 gm.). The movements of the gastrointestinal tract were satisfactory. The skin and subcutaneous tissues did not heal, but the fascia remained closed. On April 5, 1951, the condition of the wound was not changed. The baby weighed 6 lb. 11 oz. (3,033.4 gm.). The infant was discharged in good condition and taking formula satisfactorily on April 13. The wound healed by secondary union. The fascial wound did not open. In March, 1953, the child was well developed and free from gastrointestinal disturbance. No further evidence of ulcer had appeared.

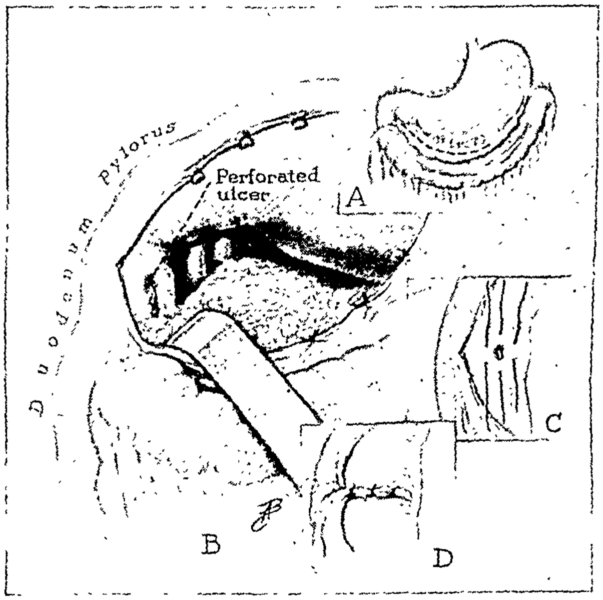

Fig. 2.—Steps in repair of perforated duodenal ulcer in infant include *A*, gastrocolic ligament cut along broken line; *B*, leaking duodenum exposed; *C*, sutures inserted; and *D*, sutures tied over portion of gastrocolic omentum.

COMMENT

The frequency of perforated ulcer in the newborn has not been established. Guthrie,[1] in 1942, reviewed the literature on peptic ulcer in infancy and childhood and found 9 instances in 6,059 postmortem examinations at the Glasgow Royal Hospital for Sick Children. Six of these were in infants under three months of age. Mavrelis and Polsen,[2] in 1948, found 59 reported instances of perforation of the stomach and duodenum before death in infants less than a year old. They noted that of 17,503 postmortem examinations performed at Cook County Hospital between 1938 and 1948, 2,319 were in infants under one year of age. Fourteen of these had perforated ulcers of which nine were in the duodenum and five in the stomach. In general, the defect was larger in the stomach than in the duodenum; those in the stomach measured 1 to 3 cm. in the greatest dimension and those in the duodenum 0.3 to 1 cm. The symptoms of perforation varied considerably. In 10, the time of perforation was evident; in 3, few or no premonitory symptoms were noted, and the infants seemed normal until found dead. In one, free perforation did not occur. Shock and sudden abdominal distention were noted most commonly. In nine, rapid onset of abdominal distention occurred but was not relieved by enema. Continuous gastric aspiration in two had little effect on the distention. Death occurred very shortly after perforation in one case, and at autopsy a gross fibrinous exudate had not yet formed. A fibrinopurulent generalized peritonitis was present in two other cases of apparent sudden death. Of those in which the time of perforation was apparent, death occurred in from 3 to 36 hours; the average, at about 12 hours.

---

[1] Guthrie, K. J.: Peptic Ulcer in Infancy and Childhood with Review of the Literature, Arch. Dis. Childhood 17: 82 (June) 1942.

In a review of the autopsy records from the Children's Hospital of Detroit from 1940 to 1949, Lemak [3] found that in 1,922 autopsies there were 18 infants under two months of age with ulceration of the gastroduodenal tract. The majority of these were under one month of age. Of these 18 infants, 4 had been examined roentgenologically. Brain damage was found in nine on postmortem examination. Six exhibited evidence of brain damage clinically by cyanosis, irritability, or convulsions. Twelve were premature infants, with a birth weight under 5½ lb. (2,495 gm.); two had clinical evidence of an active infection on admission to the hospital; eight were vomiting on admission; and hematemesis developed in six of those vomiting on admission. Ulcerations were in the stomach in 17 cases and in the duodenum in only one. The incidence of gastric and duodenal ulcers in this series is at marked variance with the incidence noted in the Cook County Hospital series.

Quinn,[4] in 1940, reported the occurrence of fatal gastroduodenal ulceration in a 6-day-old and two 5-day-old babies. The first received no roentgen examination or surgery and died 24 hours after onset of symptoms. A roentgen examination of the abdomen of the second infant showed no diagnostic signs of perforation; however, at surgery, perforation of the first part of the duodenum was found. At the age of two days, the third newborn was examined roentgenographically and a pneumoperitoneum was demonstrated. The diagnosis of a ruptured viscus was made. At operation, a perforated ulcer of the stomach was found and closed. The patient died at the age of five days because of complicating pneumonia. This report emphasizes the diagnostic and therapeutic problems worthy of consideration.

Pendergrass and Booth,[5] in 1946, reported on a 3-day-old infant with two perforations of the stomach. One of the perforations was closed surgically, but the other, on the posterior wall of the stomach, was not found until autopsy; the infant died on the fifth day of life as a result of fibropurulent peritonitis. The appearance at autopsy suggested that the second perforation was present at the time of operation and was overlooked because of its position and because, when one perforation was found and closed, an inadequate search was made for another perforation. Herbut [6] was the first to report an instance in which a congenital defect of the musculature of the stomach wall was considered responsible for the perforation. Burnett and Halpert [7] reported perforation of the stomach in a 2-day-old infant with atresia of the pyloric portion of the stomach. The principal predisposing factor in this case was believed to be a congenital defect of the muscle coats of the stomach. This case is of particular interest in that there was no distal obstruction in any of the previously recorded instances of perforation of the stomach, and there was no perforation in the two previously reported cases of obstruction.

The first report of survival after an operation for perforated ulcer in an infant was by Selinger.[8] That perforation was treated by primary closure. Bird, Limper, and Mayer,[9] in 1941, reported on a 34-hour-old baby operated on immediately after roentgen diagnosis of a ruptured viscus, based on the presence of air and fluid in the abdomen. A duodenal ulcer was closed, and the patient survived without any residual gastrointestinal deformity.

Recently, Fell, Johnson, and Kerrigan,[10] in a study of spontaneous pneumoperitoneum in the newborn, noted perforations of the large bowel in several, but in one they found and closed a duodenal ulcer with survival of the patient.

As to etiology, Mossberger [11] presented an instance of perforated duodenal ulcer in a 5-day-old infant with a hamartomatous growth of the tuberal region of the hypothalamus. In the newborn, the simultaneous existence of two minute, well-defined morbid conditions in anatomic regions far removed but long suspected of being intimately related emphasizes the need for careful necropsy examination of both the head and abdomen when a lesion is found in the upper alimentary tract or in the hypothalamus.

The matter of gastric acidity during early infancy was investigated by Miller.[12] The maximum acidity is usually reached within 24 hours after birth. Thereafter, it falls during the first 10 days, and then gradually rises until, at the end of the first month, it levels off. It has been observed that nearly all unfed infants have free acid in their gastric secretion at the time of birth and also that the heavier the infant is at birth, the more likely it is to have a more acid gastric secretion.

SUMMARY AND CONCLUSIONS

Recovery of a newborn from surgery for closure of a perforated duodenal ulcer is reported. Shock and distention not relieved by enema or gastric suction suggest the diagnosis of perforated viscus.

The value of roentgenographic examination in detecting a pneumoperitoneum is emphasized; it is the most important diagnostic aid. Experience has shown that failure to use this method of examination has been responsible for misdiagnosis or failure in recognizing the nature of the condition. At surgery, examination of both surfaces of the stomach and duodenum should be done lest a posterior perforation be overlooked or a second opening neglected. A distinction should be made between perforation of an ulcer and rupture of a viscus due to trauma, defect in the wall of the viscus, or any other cause.

BLASTOMYCOSIS IN TUBERCULOUS PATIENT

A. W. Stillians, M.D.
and
H. E. Klemptner, M.D., Chicago

The complication of pulmonary and laryngeal tuberculosis by blastomycosis is rare and, so far as we can determine, has not been reported previously. It presents several problems of interest.

REPORT OF A CASE

A 31-year-old tool grinder was admitted to the Municipal Tuberculosis Sanitarium of Chicago on Aug. 1, 1946. His illness had begun in 1935. On admission, he had far advanced pulmonary tuberculosis, with infiltrations in the upper two-thirds of both lungs, cavities bilaterally, and moderately severe tuberculosis of the larynx. Sputum contained tubercle bacilli. In the six months after admission, he made some improvement; his weight increased from 120.5 to 135.5 lb. (54.63 to 61.43 kg.), but the sputum continued to show bacilli.

Late in February, 1947, an eruption developed on the skin of the left side of the patient's nose suggestive of infection. Hot wet packs applied frequently for two weeks had no beneficial effect, and the eruption spread over the distal third of the nose to form a large granulomatous mass. Penicillin given in doses of 250,000 units for 12 days was also ineffectual. A second lesion, which looked like a small abscess but which was not acutely inflamed, appeared on the scalp above the left ear. The diagnosis of blastomycosis was made and confirmed by direct examination of the pus and by culture and histological examination of skin sections.

Iodine medication was suggested, but was thought to be too dangerous by some in view of the pulmonary infection. Treatment was begun with copper sulfate as suggested by Bevan[1] in 1905. In spite of this, other blastomycotic abscesses had appeared on the scalp and right knee, wrist, and arm in two weeks. A trial course of therapy with sulfadiazine was also ineffectual. Sulfapyridine caused malaise and vomiting. The case was discussed at a staff meting at which it was decided to try therapy with iodine cautiously. After the patient was given potassium iodide orally, up to 15 grains (0.97 gm.) three times a day, and after Lugol's (strong iodine) solution was applied locally, the lesions gradually receded and left a scar on the nose. A small focus remained at the nares for a long time. During the next six months the patient gradually lost 15.5 lb. (7.03 kg.), a drop from 135.5 to 120 lb. (61.43 to 54.4 kg.).

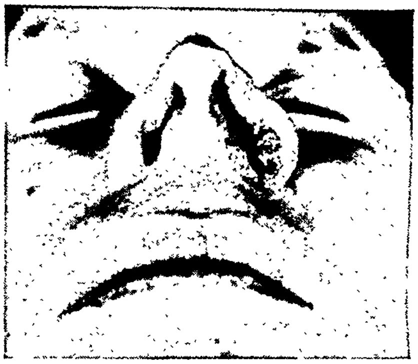

Fig. 1.—Appearance of blastomycotic lesion before treatment with ethyl vanillate.

In March, 1948, eight months after iodine treatment was begun, streptomycin, 0.5 gm. administered intramuscularly each day, was given for 60 days in conjunction with oral administration and local application of iodine. In six weeks of this treatment, the patient gained 3 lb. (1.3 kg.); after five months, he weighed 128.75 lb. (58.44 kg.); and, by March, 1949, he weighed 142 lb. (64.4 kg.), his normal weight.

Only six months later did we read of the experimental work done by Woody and Avery[2] on tuberculous guinea pigs. They showed that the combination of iodine and streptomycin gave far better results in the treatment of systemic tuberculosis of guinea pigs than did streptomycin alone.

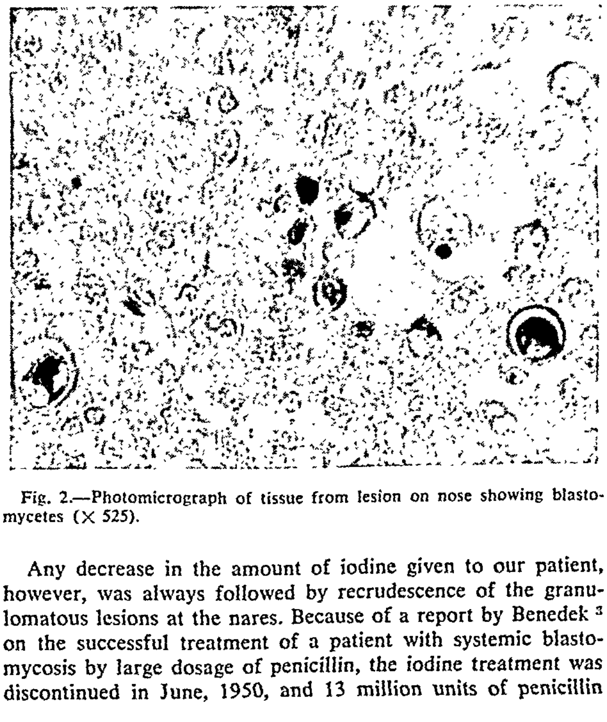

Fig. 2.—Photomicrograph of tissue from lesion on nose showing blastomycetes (× 525).

Any decrease in the amount of iodine given to our patient, however, was always followed by recrudescence of the granulomatous lesions at the nares. Because of a report by Benedek[3] on the successful treatment of a patient with systemic blastomycosis by large dosage of penicillin, the iodine treatment was discontinued in June, 1950, and 13 million units of penicillin

was given intravenously in six weeks. This had no effect on the blastomycosis; the lesions at the nares slowly increased in size. Soon after this, a second course of therapy with streptomycin was begun; 0.5 gm. was given intramuscularly each day for 60 days. At the same time, iodine treatment, as described before, was resumed. Rhinorrhea became troublesome but was controlled by daily doses of tripelennamine (Pyribenzamine). The blastomycotic granulations again decreased in size. The patient's weight remained at 142 lb. His urine on Aug. 3, 1951, contained 400 mg. of albumin per 100 cc., with a few cylindroids.

Since we had read about the inhibitory effect of ethyl vanillate on fungi in vitro,[4] we obtained a supply of this drug from the Institute of Paper Chemistry at Appleton, Wis. (Ethyl vanillate is a by-product of the manufacture of paper.) At this time the lesions were as shown in figures 1 and 2. At first, a dose of 4 gm. per day was given, and this was cautiously increased until, on Oct. 18, the blood level of 7 mg. per 100 cc. was reached. Then the dose was increased to 30 gm. per day (60 half gram capsules), and the blood level was brought to 20 mg. per 100 cc. on Oct. 25 and 30. The lesions did not recede. Because such large amounts of the drug interfered with the patient's appetite, the administration of ethyl vanillate was ended.

On Nov. 9, 1951, the patient's urine contained one gram of albumin per 100 cc., casts and cylindroids, and a few red blood cells. On Nov. 20, the blood contained 42 mg. of nonprotein nitrogen; 0.57 gm. of fibrinogen; 4.06 gm. of albumin; 2.6 gm. of globulin (ratio 1:56); and 7.23 gm. of total proteins per 100 cc. Total cholesterol was 170 mg. and cholesterol esters 75 mg. per 100 cc., thymol turbidity 3 units, and cephalin flocculation 2+. On Nov. 28, 1951, results of a Congo Red test for amyloid was positive; 100% of the dye was removed from the serum in one hour. There was no dye in the urine.

The report of Schoenbach, Miller, Ginsberg, and Long[5] on the treatment of systemic blastomycosis with Stilbamidine (4,4'-stilbenedicarboxamidine) encouraged us to try that drug, in spite of its known danger. Merck and Company furnished the drug, and its use was begun on Nov. 27 with an intravenous injection of 0.05 gm. in 200 cc. of 5% glucose in water. The second dose, 0.1 gm. in the same amount of glucose solution, was given on Dec. 1, 1951. Eight subsequent doses consisted of 0.15 gm. diluted in the same way. The last injection of the series was given on Dec. 12, and, on this day, it was noted that the lesion at the nares was only one-third as large as it had been. By Dec. 27, no untoward symptoms had appeared. On Jan. 17, 1952, a second course of treatment with Stilbamidine was begun; 0.15 gm. in 200 cc. of 5% glucose solution was given daily except for two Sundays. The 10th and last dose was given on Jan. 29. On Jan. 23, there was very little remaining evidence of blastomycosis, and, on Feb. 20, erythema and slight elevation of the skin were all that could be seen. On March 5, 1952, these had disappeared and, by February, 1953, there had been no sign of recurrence (fig. 3 and 4).

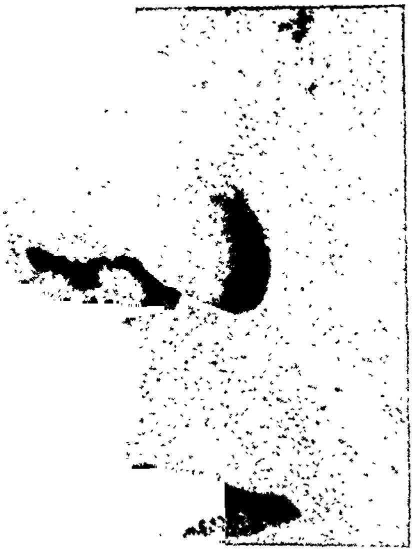

Fig. 3.—Scar of original blastomycotic lesions on nose and cheek.

On May 7, 1952, the patient reported numbness of his upper lip. This numbness was spreading laterally to the ears and upward to the frontal hair line. Slight itching was noted after the skin was stroked. Sharpness and dulness could still be distinguished. On May 9, the Congo Red test for amyloid was repeated and gave the same fully positive result as before. On Nov. 19, 1952, the paresthesia had lessened. The nares were still normal except for scars.

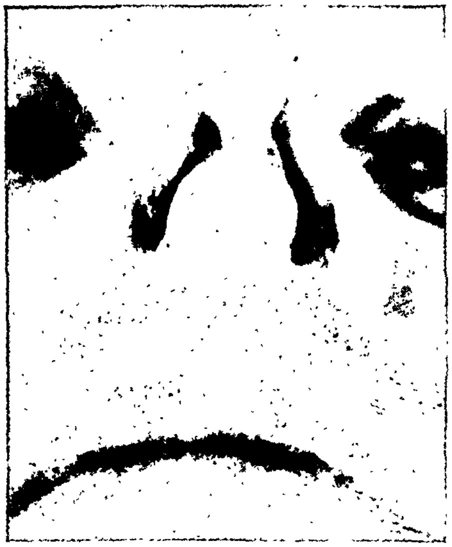

Fig. 4.—Appearance of nares after healing.

SUMMARY AND CONCLUSIONS

We consider this case of interest because of the coincident infections (tuberculosis and blastomycosis), the administration of iodides without injury to a patient with pulmonary tuberculosis, the excellent synergistic action of iodine and streptomycin, and the effective action of Stilbamidine on blastomycosis, with no untoward result except mild, temporary paresthesia in spite of preexisting albuminuria and amyloidosis.

We acknowledge that we cannot prove a cure, but absence of the disease for 13 months without treatment and without signs of recurrence makes it highly probable.

We believe that every paper dealing with Stilbamidine should emphasize that only freshly prepared solutions should be used and that a careful watch should be kept for signs of kidney or liver disturbance.[6]

Laboratory Tests.—False positive tests are the bane of the pathologist's work. They occur with all examinations performed in the laboratory. Much has been written in recent years of false positive Wassermann tests, to mention one example, and now we find that large doses of penicillin may give urinary reactions for albumin and glucose when both those items are actually absent.—E. Kellert, M.D., Laboratory Tests vs. Stethoscopes, *American Practitioner & Digest of Treatment*, July, 1953.

SIMPLE COUPLING DEVICE FOR POLYETHYLENE CATHETER

Ralph W. Alman, M.D.
and
Frederick G. Whoriskey, M.D., Cambridge, Mass.

With occasional exceptions in which knowledge is sought for its own sake, the ultimate purpose of research is the practical application of the principles investigated. The clinical use of research apparatus is often limited, however, by cost and highly specialized design. An inexpensive and simple means for connecting polyethylene tubing between 1.22 and 1.7 mm. (0.048 to 0.067 in.) in outside diameter to Luer-hub needles of any gage was developed in connection with investigations of cerebral hemodynamics. It was subsequently pointed out that the method would have definite clinical value, particularly in pediatrics, in situations in which such connections now require specially constructed needle hubs that often have numerous parts or relatively expensive, bulky, heavy adapters.

DESCRIPTION

Only two parts are needed to connect polyethylene catheters in the sizes mentioned to Luer-hub needles; an ordinary Luer-slip adapter (subsequently referred to as an impactor) from a 30 or 50 cc. syringe and a small bushing or gasket made by cutting off a 2 to 5 mm. length of rubber "uterine supporter" tubing; this material, used in conjunction with cup-and-belt pessaries, is commonly available in the operating room where it is often used to support "stay" or "tension" sutures. The rubber tubing measures 4.37 mm. (0.172 in.) in outside diameter and has a bore of 1.59 mm. (0.063 in.).

To prepare the attachment device, the impactor is slipped onto the catheter, the Luer-slip toward the junction end. Next, the junction end of the catheter is pushed through the gasket for 2 or 3 cm. and is then cautiously advanced to a match flame. The polyethylene will melt and retreat symmetrically along the outer surface of the catheter; after two or three seconds, when a sharp, solid flange or rim about 0.5 mm. thick has formed, the catheter tip is moved away from the flame and is allowed to cool for at least a minute. Finally, the gasket is pushed snugly against the newly formed flange, and the completed assembly is sterilized in a bland germicidal solution. It should be noted that formation of a flange of this size does not appreciably flare the catheter tubing or reduce the lumen diameter. The plastic material is not charred by the small amount of heat employed.

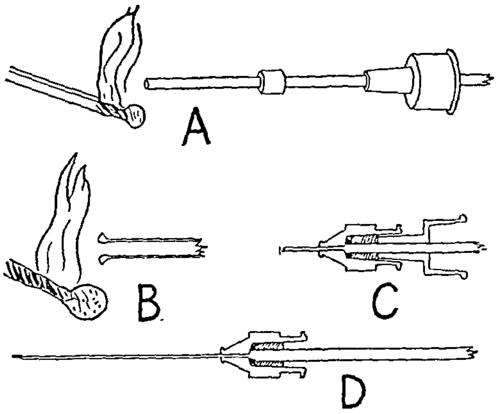
In use, the catheter is washed with sterile saline solution as are the junction end and the impactor. Coupling to any Luer-hub needle is performed merely by twisting the impactor to force the flanged junction end and gasket into the needle hub. The impactor is then removed by sliding it back along the catheter and off the unprepared end, or it may be left at any point on the tubing at which its weight will not cause inconvenience.

DURABILITY TESTS

Although the coupling has been found completely satisfactory in clinical use, it was deemed advisable to determine roughly the limits of stress that it could be expected to withstand. Because 1.7 mm. polyethylene tubing, which accepts an 18 gage needle, appears to be the size most commonly used, only this size was formally tested. A few cursory experiments with 1.22 mm. tubing indicated that a satisfactory seal is obtained with this smaller size because the rubber gasket is compressed by the tapering Luer-hub of the needle to which attachment is made.

Resistance to internal pressure was determined in 10 samples connected first dry and then wet to new and previously used needles, with gaskets ranging from 2 to 5 mm. in length. In no instance did the junction permit leakage of air or water under a pressure of 300 mm. Hg maintained for five minutes nor did disruption occur. Enough force could not be exerted manually against the plunger of a 5 cc. syringe to cause leakage of water or separation at the connection, although disruption could be caused by exerting great force on a 2 cc. syringe plunger; there was no leakage until the instant of disruption.

Resistance to possible entrance of air through the coupling was tested in the same samples. No demonstrable entrance of air occurred in any sample under negative internal pressure of 260 mm. Hg maintained for five minutes. Infiltration of air did not become apparent when maximum suction was applied to a 50 cc. syringe for one minute.



Steps in preparation of Luer coupling device: *A* and *B*, formation of flange; *C*, impaction of coupling into needle hub; and *D*, completed junction, with impactor withdrawn.

Mechanical strength of the coupling was tested by means of a spring scale calibrated against known weights. One sample, incorporating the shortest gasket, 2 mm. in length, and a new needle, both assembled dry, pulled apart consistently when a tension of 500 gm. was applied. Surprisingly, wet assembly, the condition encountered clinically, invariably nearly doubled the force required to separate the coupling. The strength of the union was also influenced by the length of the gasket; a 4 mm. gasket (the optimum) required a 700 gm. force to separate it from the needle if it had been connected dry and a 1,200 gm. force if it had been connected wet. When a coupling was attached wet to a previously used needle, the hub of which was internally scored by repeated attachment to syringes, the polyethylene tubing was cold-drawn to capillary thinness by tension before the connection separated.

COMMENT

Durability tests indicate that the coupling will neither leak nor separate under the greatest internal pressures likely to be applied in clinical use and that there is no hazard of air being admitted into any system in which such a coupling is used. These properties were not impaired by lack of care in preparing the gaskets, the faces of which were usually not exactly parallel, precisely plane, or very regular. All gaskets tested were cut with scissors. Although separation by mechanical tension could be completely prevented by substituting for the impactor a lock-type adapter with a shortened tip, this would require gaskets of precise length and would add unnecessary weight to the needle hub. Any force capable of separating the simpler coupling would undoubtedly first pull the needle from its insertion.

Absence of bulk and appreciable weight makes this coupling ideal for infusions in infants, where a length of very flexible small-bore tubing between needle and syringe will permit considerable movement of both patient and operator without dislodging the needle; metal adapters are heavy enough to pull out the needle by their weight combined with that of the hub. Additional advantages of the gasket attachment are that the lumen is not narrowed at the connection and that the junction will not leak after frequent use, as it will when the tubing of a hypodermic needle is repeatedly inserted into the catheter end. The cost of the gaskets is negligible, and an impactor becomes available each time a 30 or 50 cc. syringe is broken. The ease of fabrication is such that many lengths of polyethylene tubing can be prepared in a very short time.

SUMMARY

A new, simple means of attaching polyethylene catheters to Luer-hub needles is described, and proof of the durability of the coupling is given. The coupling is easily and quickly fabricated, negligible in cost and bulk, and very light in weight.

TRANSRECTAL BIOPSY OF THE PROSTATE

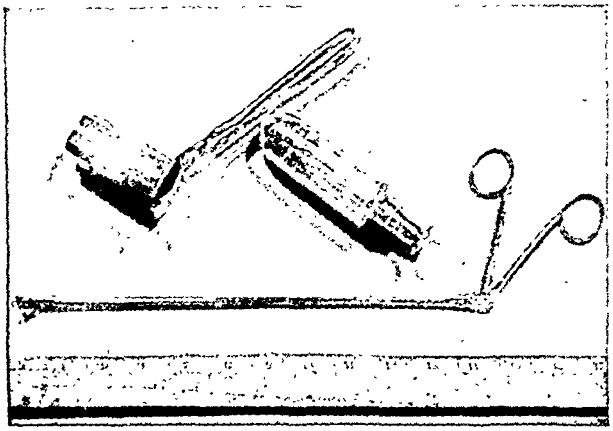
Harry Grabstald, M.D., Cleveland
and
James L. Elliott, M.D., New Orleans

There are indications for biopsy of the prostate when formal perineal exposure is not desirable, necessary, nor, on occasion, possible. The purpose of this report is to present a simple method for securing adequate prostatic tissue for biopsy. This technique was first used by one of us (J. L. E.) in 1947. The procedure has recently been followed in over 50 cases, without complications of any type; there have been no fistulas. We are unable to find reference to this technique in the literature.

TECHNIQUE

In this procedure saddle block anesthesia is preferable because of the degree of anal relaxation required. Biopsy tissue is secured with the patient in a modified jackknife position. The instrument utilized is the Fansler operating rectal speculum (see figure).* The wide caliber of the instrument permits ready palpation of the prostate and manipulation of the biopsy forceps through the lumen. Attempts to use simple anal specula or proctoscopes will likely result in failure, since most of them are designed for diagnosis and not for manipulative procedures.

Preliminary anal sphincter dilatation is important. As yet sphincterotomy has not been done, but were this necessary it would add no hazard to the procedure. The instrument is introduced and the obturator withdrawn. The end is pushed taut over the suspicious area involved, which is palpated without difficulty. A 1 cm. incision is made through the rectum with a pointed blade. The index finger is inserted through the rectum and the nodule palpated again. We utilize large, relatively nonflexible biopsy forceps (see figure) to remove bites of tissue 0.5 to over 1 cm. in size; the type of forceps used in cystoscopic biopsy did not prove satisfactory. The nodule can be easily palpated after each bite and biopsies repeated at the operator's discretion. We routinely remove four to eight fragments. The operating time is three to seven minutes. After the initial rectal incision is made, there is rarely even moderate oozing. This is easily controlled by pressure until the tissue is removed, after which suturing is done with a 00 chromic absorbable surgical, figure-of-eight or continuous suture. A 4 cm. by 8 cm. gauze bandage is placed over the biopsy site, with one end protruding from the anal orifice. This is removed the following morning.



Fansler operating rectal speculum and biopsy forceps.

Thorough preoperative catharsis is recommended. Streptomycin or phthalylsulfathiazole (Sulfathalidine) has been administered orally in many patients. The course has been an uneventful one in those to whom no oral medication has been given. We have used low residue or even clear liquid diets postoperatively. Again, the course has been no different in those who have had bowel movements the first postoperative day.

REPORT OF CASES

CASE 1.—A 64-year-old white man was admitted with a suspicious isolated stony hard prostatic nodule. A biopsy was made, using the described technique, and resulted in a diagnosis of carcinoma. Five days later, on Nov. 25, 1952, radical perineal prostatectomy was carried out. The rectum was examined at the conclusion of surgery, before closure, and there was no evidence of tear at the previously biopsied site. The catheter was removed on the 17th postoperative day, and there was minimal urinary incontinence. By the time of discharge, on the 24th postoperative day, the patient was no longer incontinent and he voided well, with good control.

---

* The Fansler operating rectal speculum is manufactured by George P. Pilling & Sons, Philadelphia.

From the Crile Veterans Administration Hospital (Dr. Grabstald), and the United States Public Health Service Hospital (Dr. Elliott).

Case 2.—A 66-year-old white man underwent transrectal biopsy of an isolated prostatic nodule, which revealed adenocarcinoma. Radical retropubic prostatectomy was performed 14 days later on April 8, 1952. During surgery the rectum previously incised for the biopsy was opened in the same area. When surgery was completed the recognized rectal tear measured 3 to 4 cm. in length. The rectum was closed in layers, with fine, chromic absorbable surgical sutures. The bladder neck was loosely sutured to the membranous urethra. Postoperatively a rectovesical fistula developed, which required colostomy and suprapubic cystotomy. On Oct. 23, 1952, the fistula was closed by perineal approach without difficulty. We feel that the fistula resulted from the rectal tear. Had this tear been made at time of radical retropubic prostatectomy, and had it not been preceded by biopsy, the same result would have been inevitable. This complication is a technical factor secondary to radical retropubic prostatectomy and not to the biopsy.

Case 3.—A 67-year-old white man underwent segmental bladder resection for carcinoma on Dec. 11, 1951. Later an isolated pulmonary metastasis developed, and the patient was subjected to lobectomy by one of us (J. L. E.). The patient is well 16 months after surgery. On his last admission a hard prostate was noted. Transrectal biopsy made on Dec. 4, 1952, was positive for adenocarcinoma. Orchiectomy was performed, and diethylstilbestrol therapy started. One of the biopsied prostatic fragments showed transitional mucosa along one edge. The biopsy report was not received for 48 hours. A urethral catheter was then inserted for 24 hours. There were no complications of any sort.

Case 4.—A 58-year-old Negro man entered with urethral stricture dilatation. Rectal examination revealed an isolated stony hard nodule in an atrophic prostate. Transrectal biopsy was positive, and on Feb. 26, 1953, nine days after biopsy, radical retropubic prostatectomy was performed. The catheter was removed on the 19th postoperative day. Except for the urethral stricture, which required dilatation, the course was without complications.

Case 5.—A 62-year-old Negro man entered with a diffusely enlarged hard nodular prostate. On the first occasion transrectal biopsy, by the assistant resident, revealed only rectal tissue. In the submucosa definite infiltrating adenocarcinoma was noted. Repeat biopsy was performed through the same route and adenocarcinoma of the prostate found. It is unusual to find a prostatic tumor invading the rectum. This would not have been noted had biopsy by any other technique been done.

Case 6.—A 78-year-old white man underwent a rectal examination on admission, which revealed a definite stony hard prostate characteristic of carcinoma. Films of the lumbar region of the spine and the pelvis revealed an area in the right ilium suspicious of metastatic prostatic carcinoma. Acid and alkaline phosphatases were normal. The prostate was biopsied by the described technique, and the sections showed severe calcium deposition. There was no evidence of carcinoma. Skull films were negative for Paget's disease. Had the diagnosis of carcinoma been made clinically on the basis of rectal examination and x-ray examination this patient would have had orchiectomy and stilbestrol therapy. As it is, further treatment is unnecessary, and in retrospect the bone lesion in the ilium probably represents Paget's disease.

In one patient a fragment of seminal vesicle was obtained on biopsy, and epididymitis later developed.

COMMENT

The treatment of choice for early carcinoma of the prostate without fixation or metastasis and with normal phosphatases is formal perineal biopsy and frozen section, followed by radical perineal prostatectomy. Radical retropubic prostatectomy has been done, but there are no five year survival figures to date that merit comparison with the perineal procedure. With the introduction of retropubic prostatectomy, it was not long before a radical retropubic approach was advocated for early carcinoma by those not trained in perineal surgery. It is not within the scope of this report to compare the merits of radical perineal and radical retropubic prostatectomy. Needless to say, the former is a procedure of proved merit, while the latter has yet to be fully evaluated. In the cases described herein, one radical perineal and two radical retropubic prostatectomies have been carried out by one of us (H. G.) following transrectal biopsy. In the first case of a radical retropubic prostatectomy, complicated by fistula formation, surgery was done 14 days after biopsy. In the second, without such complication, a period of only nine days elapsed, thereby not justifying a longer waiting period. The difference lay in the fact that in the former case the rectal mucosa was exposed. Radical perineal prostatectomy was done five days after biopsy, without complication.

The obvious disadvantage of the retropubic approach is that operative biopsy with frozen section is not feasible. The suspected nodule noted on rectal examination is in the posterior lamella, while the operative exposure is anterior. Reports of radical retropubic prostatectomy for "suspected" carcinoma in which the removed tissue is benign are not too uncommon.

Perineal punch biopsy has been used to obviate this tragedy, but this technique has obvious shortcomings, most important of which is the incidence of false negative biopsy reports. As is well known, a negative report following perineal punch biopsy does not eliminate carcinoma. There are no figures to date concerning incidence of false negative perineal punch biopsies as proved by formal perineal exposure with repeat biopsy. The importance of such a correlative series is obvious. Hudson[1] is, at the present time, compiling statistics that reveal the incidence of false negative biopsies to be extremely high. The incidence of false negative reports with the frozen section method are also significant.

A transrectal approach to prostatic biopsy may be of special value in the following instances: 1. Positive biopsies can be secured before radical surgery, either retropubic or perineal, is carried out. Many patients will not consent to radical surgery unless a preoperative diagnosis is made, and many will not consent to orchiectomy without a definitive diagnosis. 2. In some hospitals frozen section techniques have proved to be unsatisfactory or are not possible at all times. 3. In many instances there are firm, but not stony hard, nodules. It has been customary to note such cases and to repeat the rectal examination in several months. In other cases estrogenic hormones have been given, with the supposition that if the nodule softens under this regimen there is added evidence favoring a diagnosis of carcinoma. Biopsy would appear to be the procedure of choice in these instances, since many are cases of early carcinoma and are amenable to radical surgery.

4. It is conceivable that the transrectal approach may be a distinct advantage in instances in which repeat biopsies are indicated, such as in research projects

---

[1] Hudson, P. B.: Personal communication to the authors.

wherein prostatic changes under specific therapy are to be followed. In other instances, for statistical reasons, a positive biopsy is mandatory before beginning treatment. We have repeated the biopsies after short intervals without difficulty. 5. Higbee [2] reported 36 radical perineal prostatectomies, of which 5 (13.8%) showed benign tissue. In these cases radical surgery was performed on the basis of suspected carcinoma, but sections revealed only benign changes. In his series of 12 frozen section biopsies, there was disagreement in 3, that is, 3 operable patients were not subjected to radical surgery on the basis of false negative frozen biopsy reports.

6. Burgess and Evans [3] described certain types of carcinoma of the prostate in which the diagnosis is difficult. In instances of unusual bony metastasis or perhaps where there is difficulty differentiating Paget's disease from prostatic metastasis, as in our case,[1] it may be difficult to determine the primary site. If there is a possibility of prostatic tumor, biopsy is mandatory. 7. Although we have had no experience in this regard, it seems reasonable that the procedure might be of value in the diagnosis of such conditions as prostatic tuberculosis and prostatic sarcoma. 8. Recently, Thompson and Albers [4] have emphasized the difficulty in clinically differentiating granulomatous prostatitis from carcinoma. It would appear that the technique described herein would be a more appropriate method than the transurethral method.

SUMMARY AND CONCLUSIONS

A technique is presented for transrectal biopsy of the prostate. This procedure is recommended as a simple diagnostic tool, which has been used in over 50 cases without complications of any sort. There have been no fistulas. Larger prostatic fragments may be secured by this technique than by any other, except open exposure. The procedure may be repeated when necessary and has been followed by radical retropubic and perineal surgery. The procedure of choice for early carcinoma of the prostate remains formal exposure, frozen sections, and radical perineal prostatectomy. For those not trained in perineal surgery, however, this technique may prevent the needless radical retropubic removal of benign prostates for "suspected" carcinoma.

Bovine Toxoplasmosis.—Toxoplasma, a protozoon heretofore not known to occur in cattle, was demonstrated in three cows, one bull, and two calves originating in four widely separated Ohio herds. Toxoplasma were recovered from two of these spontaneously infected calves and one cow by the mouse transfer technique and were demonstrated histologically in lesions of all six animals. . . . Bovine toxoplasmosis can conceivably be of public health significance, since Toxoplasma were demonstrated in the milk as well as edible portions of the beef carcass. In addition to milk, feces and sputum may be potential sources of infection for man and animals since Toxoplasma were found in pulmonary and gastrointestinal lesions.—V. L. Sanger, D.V.M., and others, Toxoplasmosis. V. Isolation of Toxoplasma from Cattle, *Journal of the American Veterinary Medical Association*, August, 1953.

Vitamin B_{12} with Intrinsic Factor Concentrate.—Bifacton (Organon).—A complex prepared from vitamin B_{12} and intrinsic factor concentrate. The latter is prepared from hog stomach.

Actions and Uses.—Vitamin B_{12}, also known as the extrinsic factor, when combined with intrinsic factor concentrate (a partially purified preparation of the intrinsic factor of Castle obtained from stomach tissue of hogs), is effective orally for the treatment of pernicious anemia with and without neurological complications. It is also effective by virtue of its vitamin B_{12} content in the treatment of tropical and nontropical sprue, nutritional macrocytic anemia caused by vitamin B_{12} deficiency, and macrocytic anemia of infancy. The intrinsic factor, which is lacking in patients with pernicious anemia, increases the efficiency of alimentary absorption of vitamin B_{12}.

Oral administration of vitamin B_{12} with intrinsic factor concentrate produces an adequate hematopoietic response in patients with pernicious anemia; therefore, it is suitable to replace injectable cyanocobalamin or liver for patients in whom parenteral therapy is difficult or undesirable. Patients should be carefully observed during oral treatment; if expected improvement does not occur, further examination should be made to rule out complicating disorders such as infection, gastrointestinal malfunction, or undiagnosed malignant disease. In the presence of any such complication, the dosage may need to be increased or abandoned in favor of injection therapy with cyanocobalamin or liver.

Vitamin B_{12} with intrinsic factor concentrate is fairly stable in dry form, but until more is known regarding the keeping qualities of the intrinsic factor, the mixture should be protected from moisture, light, and heat above 45° C. The mixture has not been reported to produce any toxic effects. The possibility of gastrointestinal allergy to hog protein, from which the intrinsic factor is derived, should be borne in mind.

Dosage.—Vitamin B_{12} with intrinsic factor concentrate is administered orally. The potency is expressed in terms of the U. S. P. oral unit of hematopoietic activity, assigned on the basis of clinical assays submitted to the U. S. P. Anti-Anemia Preparations Advisory Board. The declaration of the amount of cyanocobalamin present in preparations of the mixture is excluded to avoid the misleading implication that this represents additional hematopoietic activity in excess of the labeled unitage.

The average daily dosage for the treatment of pernicious and related macrocytic anemias is 1 U. S. P. oral unit daily, in two divided doses of one-half unit each before the morning and evening meals. In severe cases, a more rapid response may be achieved with an initial daily dosage of 2 U. S. P. oral units, also given twice daily in equally divided doses for the first one or two weeks of therapy. Reticulocyte values usually rise to peak levels within 5 to 12 days. Values for other formed elements of the blood approach normal within 8 to 10 weeks. Megaloblastic bone marrow may return to normal within a few days. Neurological complications usually are relieved within a period of 1 to 12 weeks, depending on their duration and the intensity of the therapy.

Organon, Inc., Orange, N. J.

Tablets Bifacton: Each tablet contains the equivalent of ½ U. S. P. oral unit. U. S. trademark 566,740.

SUPPORT NEEDED FOR "BRICKER AMENDMENT"

For several months the press has carried accounts of the political "hassle" that has developed over a resolution introduced by Senator Bricker of Ohio proposing a constitutional amendment limiting the effects of treaty law. Inasmuch as this resolution would also apply to conventions of such groups as the International Labor Organization, the American Medical Association has been active in its support. Because of recent attempts to circumvent the purpose and intention of the resolution, it is important for the medical profession to know the facts and to renew its efforts to effect passage of Senator Bricker's proposal.

On Jan. 7, 1953, Senator Bricker and 63 cosponsors introduced S. J. Res. 1, 83rd Congress, which recommended that a constitutional amendment be adopted protecting the states and the people from abuse of the treaty making authority. This resolution was referred to the Senate Judiciary Committee together with S. J. Res. 43 (sponsored by the American Bar Association). On June 15, 1953, the committee submitted a favorable report on S. J. Res. 1, with amendments, and recommended that it be adopted. The amended version of the resolution, as approved by the committee, removes any possible doubt as to whether a treaty must be consistent with the Constitution. It stipulates that no provision of a treaty that violates the Constitution or that is inconsistent with the nature of the government of the United States shall be valid. It establishes by unequivocal language that the treaty power cannot be used for purposes in conflict with the Constitution. It also provides that a treaty shall become effective as internal law in the United States only through the enactment of domestic legislation that could have been adopted in the absence of a treaty.

In view of the fact that treaties and executive agreements have become wholly interchangeable instruments of national policy, it would be useless to adopt a constitutional amendment limiting the more difficult treaty method of concluding international agreements without defining the power of Congress to control the less difficult method. The resolution thus would subject executive and other agreements to regulation by the Congress and to the limitations imposed on the making of treaties.

S. J. Res. 1, as reported, will not affect the present method of negotiating and ratifying treaties. Treaties will continue to be negotiated by the President and ratified with the advice and consent of two-thirds of the Senators present and voting. The amendment will not prevent the President and the Senate from concluding a treaty otherwise valid under the Constitution on any subject whatsoever, nor will it affect in any manner treaties that do not make internal law in the United States. It will, however, make impossible the participation of any foreign nation by treaty method in the adoption of laws for the regulation of the conduct of the citizens of the United States. It will prevent the reduction of state power and the enhancement of federal power at the expense of the states through the ratification of a treaty. The balance of power between the states and the federal government will be subject to change only by the regular processes of constitutional amendment or judicial interpretation. The resolution will not render acts of Congress unconstitutional that have been adopted under a treaty concluded prior to the ratification of the proposed constitutional amendment; however, legislation enacted after the adoption of the amendment, in implementation of a treaty, will be subject to the provisions of the amendment irrespective of whether the treaty antedates the amendment.

During the closing days of the first session of the 83rd Congress, Senator Knowland of California introduced an amendment to S. J. Res. 1 (in the nature of a substitute), at the request of the administration, which differs from the Bricker Resolution in the following important respects: The Knowland proposal provides that a treaty shall become effective as internal law only through the enactment of appropriate legislation by the Congress "*when the Senate so provides in its consent to ratification.*" This is an old and discarded approach to the problem and one that involves no protection for American rights beyond what the American people now have —which protection depends on the Senate.

When ratifying a treaty, it will be necessary, under this proposal, for the Senate to determine whether anything in the fine print adversely affects domestic law and then include a reservation that such provision shall not become effective until implemented by legislation. Modern treaties are long and involved. Senators often do not have time to read and consider carefully provisions that may have been put into them affecting domestic law. In no other major country in the world is a treaty self-executing. In every other major country treaties require implementation by enactment of domestic legislation. It should not be left to the discretion of the Senate whether the House of Representatives shall be allowed to participate in making domestic law within the United States. This participation should be mandatory.

The Knowland proposal is in sharp contrast with the purpose of the Bricker amendment, which would safeguard the American people against living under laws imposed by international authority, particularly when such laws take precedence over and even conflict with our own American laws, including the Constitution of the United States. It is important, therefore, that members of the Senate and the House of Representatives be contacted while they are at home and before the second session of the 83rd Congress convenes and advised of the endorsement and active support of the medical profession of S. J. Res. 1 as reported by the Senate Judiciary Committee.

BILATERAL ADRENALECTOMY FOR CUSHING'S SYNDROME

Cushing in 1932 described a clinical entity characterized by the "moon face" appearance due to abnormal deposition of fat over the face and neck, the "buffalo hump" caused by a pad of fat over the cervicothoracic vertebrae, and, in contrast to the obesity of the upper half of the body, thin, weak extremities. The skin in these patients is thin, with distinctive purplish striations. Accompanying this characteristic appearance are hypertension; osteoporosis; ecchymosis; diabetes, frank or latent; amenorrhea; and diminished libido or impotence in men. Frequently there is hirsutism and acne. Cushing believed that this entity was caused by a pituitary adenoma or pituitary basophilism. Recent studies in endocrinology and in steroid chemistry have established that the so-called Cushing's disease is caused by hyperfunction of the adrenal cortex. The term Cushing's disease is now restricted to the few cases of Cushing's syndrome associated with basophilic adenoma of the pituitary, which is believed to stimulate the cortical adrenal secretions.

The pathological changes in the adrenals of Cushing syndrome are of three types: (1) adrenal hyperplasia without tumor, (2) hyperplasia with benign tumor of the adrenal cortex, and (3) hyperplasia with malignant tumor of the adrenal cortex. Hypersecretion of the adrenal 11-oxysteroids, particularly of corticosterone and 17-hydroxycorticosterone, are believed to account for most of the pathological and physiological changes in Cushing's syndrome. The cause of hyperadrenocorticism in the majority of patients with the Cushing syndrome is bilateral adrenal hyperplasia with no evidence of pituitary tumor. Most of the clinical and laboratory features of the syndrome have been reproduced by stimulation of the adrenal cortex with corticotropin or by administration of large doses of cortisone.

Priestley and co-workers [1] report on 29 patients with Cushing's syndrome operated on at the Mayo Clinic from 1945 to 1951. Surgical exploration in these cases failed to reveal a tumor of the adrenal cortex. There were 6 males and 23 females. With the preoperative and postoperative use of cortisone in nine of the patients, the immediate postoperative shock-like reaction was averted, in all but one case, without the use of aqueous adrenal cortical extract. These authors state that administration of cortisone for 24 to 72 hours will relieve the delayed reaction, and nausea, vomiting, anorexia, fever, and tachycardia disappear. Six of the 29 patients died. There have been no deaths in the last 10 cases. Nineteen patients obtained excellent remissions from Cushing's syndrome. These authors conclude that the clinical syndrome, whatever the primary cause, is dependent on hyperfunction of the adrenal cortex, and that their results indicate that the features of Cushing's syndrome can be relieved by removal of most of the adrenal cortical tissue. They also stress that hyperfunction of the adrenal cortices can exist in the absence of gross enlargement of the adrenal glands. Their practice was to perform an extensive subtotal resection of one adrenal gland and subsequently total removal of the other adrenal gland. They state that about 90% of one adrenal should be removed and a total adrenalectomy performed on the other side.

Poutasse and Higgins,[2] in a recent communication, report on 28 patients with Cushing's syndrome operated on in the Cleveland Clinic. Four of these had an adrenal adenoma, two had a malignant cortical tumor, and two more had small adenomas of the adrenal. The remaining 20 had normal-sized or enlarged adrenals.

Laboratory aids in diagnosis of adrenal tumor are the excretory urogram, perirenal gas insufflation, and translumbar aortography. These authors emphasize the protective influence of cortisone given prior to adrenal surgery. Operative stability is provided by administration of 100 mg. of cortisone intramuscularly about 12 hours before the operation, which is repeated again a few hours before the operation. This should be continued after operation in doses of about 50 mg. every 6, 8, or 12 hours as necessary. The dosage should be gradually reduced, and within three to six weeks there should be no further need for the drug. Signs and symptoms of adrenal insufficiency must be carefully watched for. These are nausea and vomiting, acne, muscle pains or stiffness, and an unexplained fever. They state that it is difficult to estimate how much adrenal tissue to leave in the body but that experience has shown that about 90% must be removed. Poutasse and McCullagh [3] emphasize that it is important to understand that Cushing's syndrome is a progressive disease that greatly shortens life expectancy. They state that surgical removal of hyperfunctioning adrenal cortical tumor usually results in remission of the syndrome and that subtotal adrenalectomy in bilateral hyperplasia also results in remission, provided sufficient adrenal cortical tissue has been excised.

The surgical therapy outlined, according to Poutasse and McCullagh, is the reflection of the present limited status of our knowledge regarding the control of the hyperfunctioning adrenal cortex. It appears to be justified in a condition that has a progressive course and that is not amenable to medical therapy.

MEDICAL NEWS

ARKANSAS

Society News.—The fifty year club of the Arkansas Medical Society has elected Dr. Merrieman L. Norwood, Lockesburg, president; Dr. Robert Caldwell, Little Rock, vice-president; and Dr. John H. McCurry, Cash, secretary-treasurer.

General Practitioners' Meeting.—The annual fall assembly of the Arkansas Academy of General Practice will be held at the Lafayette Hotel, Little Rock, Oct. 14-15. Out-of-state speakers will include Drs. Hampton C. Robinson, Houston, Texas, and Albert S. Dix, Mobile, Ala.

Personal.—Dr. Charles G. Leverett, McGehee, was recently elected to the McGehee school board.——Dr. Julius H. Hellums, Dumas, has been elected president of the Dumas Lions Club.——Dr. Hayden C. Nicholson, dean of the University of Arkansas School of Medicine, Little Rock, was recently elected chairman of the Community Council of Greater Little Rock.——Dr. Torrence J. Collier, Hot Springs National Park, was awarded the distinguished service plaque by the Arkansas Medical, Dental and Pharmaceutical Society "in appreciation of his unusual service rendered to the association." Dr. Collier, who served as president of the society in 1937, has been chairman of the exhibit and awards committee, which he created, for the past 15 years.

CALIFORNIA

Society News.—The Alameda-Contra Costa Medical Association, the Blood Bank, and the Bureau of Medical Economics recently moved to their new headquarters building at 6230 Claremont Ave., Oakland.

Physicians' Orchestra.—Dr. Reuben Straus, Los Angeles, has issued a call to musician members of the Los Angeles County Medical Association to form a symphony orchestra. The group will have free use of a large auditorium for rehearsals and of a fine library of symphonic music, belonging to a nationally prominent conductor who will direct them. Dr. Straus urges that those interested call him at Charleston 8-5531 or Crestview 4-6327.

Medical Photography Class.—Open to all persons interested in the details of medical photography, a University of California extension course in photography in medical practice and research will meet on Wednesdays at 7:30 p. m. in room 191 of the Business Administration and Economics Building at University of California at Los Angeles. Requests for information should be directed to Dr. Thomas H. Sternberg, Head of Postgraduate Instruction, Medical Extension, University of California, Los Angeles 24 (ARizona 7-4201).

ILLINOIS

Dedication of Psychiatric Research Laboratory.—The Thudichum Psychiatric Research Laboratory will be dedicated at the State Research Hospital in Galesburg, Oct. 17. Dr. Richard J. Graff, superintendent of the hospital, will be chairman during the morning session, which will begin at 10:30. Gov. William G. Stratton, Dr. Otto L. Bettag, director of the state department of public welfare, Springfield, and Dr. Percival Bailey, Chicago, research consultant of the department, will make the opening addresses. Dr. David McK. Rioch, technical director, neuropsychiatric division, Army Medical Service Graduate School, Washington, D. C., will read a paper "The Brain and Consciousness." Chairman of the afternoon session, 2:30 p. m., will be Dr. Ralph W. Gerard, Chicago, consultant in research, department of public welfare. Dr. Seymour S. Kety, associate director, in charge of research, National Institute of Mental Health, Bethesda, Md., will discuss "Circulation and Metabolism of the Human Brain," Dr. Wilhelm S. Feldberg, head of the physiology and pharmacology laboratory, National Institute for Medical Research, London, England, "Some Aspects of Chemical Transmission in the Central Nervous System," and Dr. D. Ewen Cameron, director, Allan Memorial Institute of Psychiatry, McGill University Faculty of Medicine, Montreal, Canada, "Extended Applications of Psychosomatic Theory in the Senium."

General Practitioners Meet in Decatur.—The annual scientific assembly of the Illinois Academy of General Practice will convene at the Masonic Temple in Decatur, Oct. 17-19, under the presidency of Dr. William H. Walton, Belleville, who will be moderator at a round-table luncheon, Sunday, 12:15 p. m., at the Hotel Orlando. A regional chapter secretaries' conference will be held, at 4:30 p. m., in this hotel, where, at 6:30 p. m., a hospitality hour will precede the annual banquet, and Countess Maria Pulaski will give her speech, "My Life as a Spy." Out-of-state speakers for the scientific sessions include:

Arthur W. Neilson, St. Louis, Industrial Dermatitis in General Practice.
Edgar S. Brintnall, Iowa City, Varicose Veins and Varicose Ulcer.
Michael Somogyi, Ph.D., St. Louis, Therapeutic Diets for Diabetes.
Wendell G. Scott, St. Louis, Pitfalls in the Diagnosis of Carcinoma of the Colon.
Paul S. Williamson, Walsh, Colo., The Future of the Younger Physician.

Drs. Robert M. O'Brien, Robert H. Ramsey, Frederick C. Reynolds, and Edmund A. Smolik, St. Louis, will participate in an orthopedic symposium Sunday afternoon.

Chicago

Sir James Ross Visits Chicago.—Sir James Paterson Ross, director of surgery, St. Bartholomew's Hospital, London, who will be the guest of the department of surgery, Northwestern University Medical School for the week beginning Oct. 12, will deliver the Charles H. Mayo lecture, "Some Unsolved Problems on the Surgery of the Sympathetic Nervous System," at 4 p. m., Oct. 12, at Thorne Hall, located on the medical school campus at the corner of Lake Shore Drive and Superior St. All physicians are cordially invited. For the remainder of the week, Sir James will be at Passavant Memorial, Wesley Memorial, and Evanston hospitals, where he will conduct operative clinics and participate in a series of ward rounds and surgical conferences.

Pediatric Research Benefit.—A luncheon and style show will be presented by the John T. Shayne Company for the Women's Faculty Club of Northwestern University Medical School, Oct. 13, 12:30 p. m. in the Terrace Casino of the Hotel Morrison. The primary purpose of the club, a service organization composed of wives of physicians associated with the medical and dental schools in a voluntary teaching capacity, and others interested in the medical program, is to stimulate community interest in the university's medical school clinics, to assist in the care of its clinic patients, and to develop new projects in clinics already organized. Club members seek to raise funds for medical research, particularly in the field of pediatrics. The group is currently sponsoring two fellowships, one in pediatric surgery, held by Dr. Roberto Ortiz, and one in pediatric medicine, held by Dr. Fern L. Stevenson, both at Children's Memorial Hospital. Tickets for the luncheon and style show are $5.50. The following prizes will be given: (1) a natural starlight ranch mink cape stole (through the cooperation of John T. Shayne), (2) an original suit by Seymour Fox (valued at $150, donated by John T. Shayne), and (3) a $100 merchandise certificate (donated by Saks Fifth Avenue).

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

INDIANA

Meeting on Air Pollution.—The Midwestern Air Pollution Prevention Association will meet at the Gary Hotel, Gary, Oct. 15-16, under the sponsorship of the Armour Research Foundation of Illinois Institute of Technology, Chicago, to discuss groundwork for a concerted two state attack on industrial air pollution.

MASSACHUSETTS

Philippine Gift in Memory of Richard Strong.—Officials and employees of the Republic of the Philippines have contributed 1,000 pesos ($500 in U. S. currency) to the Harvard School of Public Health, Boston. In making the gift, which will go toward the Strong Professorship of Tropical Public Health, Dr. Juan Salcedo Jr., secretary of the Department of Health of the Republic of the Philippines, noted that the money had been raised through voluntary contributions from officials and employees of the Philippine department of health. "While the amount of our contribution is modest," he wrote, "our feelings for the purpose of the fund are strong. We recall with a deep sense of gratitude the many years of devoted service of the late Colonel Richard Pearson Strong in the Philippines."

Commissioned in the Army Medical Corps and sent to the Philippines during the Spanish-American War, Dr. Strong became the first president of the Army Medical Research Board, established to study tropical diseases, and discovered the dysentery bacillus that bears his name. In 1902, he resigned his commission to serve the Philippine government and for 11 years was director of the biological laboratories of the Philippine Bureau of Science as well as chief of the medical department of the Philippine Islands General Hospital and professor of tropical medicine at the University of the Philippines. Returning to the United States in 1913, he became professor of tropical medicine at Harvard, a position he held until he became emeritus professor in 1938. Dr. Strong's contributions to the knowledge of sleeping sickness, yellow fever, and malaria in the Belgian Congo from 1926 to 1927 and in 1934 prompted the Belgian government last year to make a gift toward the Strong Professorship.

MICHIGAN

Nutrition Day.—Michigan Nutrition Day will be observed, Oct. 12, under the sponsorship of the Michigan Nutrition Council and Michigan State College, East Lansing, where a program, "Our Changing Food Supply," will be presented in the auditorium building (morning sessions) and at the Kellogg center (luncheon and afternoon sessions). Leonard A. Maynard, Ph.D., director, School of Nutrition, Cornell University, will talk on world food problems at the opening session. Elmer M. Nelson, chief, division of nutrition, Food and Drug Administration, Washington, D. C., will present "The Philosophy of Food Fortification" at the luncheon meeting, 12:30 p. m., and will also participate in a panel on food fortification, 2-4 p. m., with Dr. John K. Altland, director, division of local health administration, Michigan Department of Health, and Miss Linnea Anderson, nutritionist, Michigan Department of Health. Other panels to be presented simultaneously are "The Soil as It Affects the Nutritive Quality of Food," "Food from the Garden to the Table," "Chemicals in Foods," and "Fluoridation of Public Water Supplies." Dr. Winston B. Prothro, public health director, Grand Rapids, will participate in the fluoridation panel.

MISSOURI

Personal.—Dr. Philip J. Aquino, Caruthersville, has been elected president of the Caruthersville Rotary Club.——Dr. Alphonse McMahon, St. Louis, who served in the Medical Corps of the U. S. Navy in World War II, recently was promoted to rear admiral, Naval Reserve Corps. In recognition of the honor, Dr. McMahon was given a reception at St. John's Hospital, where he is chief of staff. Dr. McMahon is president-elect of the Southern Medical Association.

Surgical Society Meeting.—The St. Louis Surgical Society will meet in the auditorium of the medical society building, Oct. 13, 8:30 p. m. The program will consist of a symposium, "Advances in Anesthesia," which will be moderated by Dr. C. Rollins Hanlon, professor of surgery, St. Louis University School of Medicine. All members of the medical profession are invited to attend dinner at the Sheraton Hotel, preceding the meeting. Reservations should be made through the office of the society, Franklin 5225. A cash bar will be open at 6:30 p. m. before the dinner.

NEW JERSEY

Lecture on Allergy.—On Oct. 15, 9 p. m., the New Jersey Allergy Society, in conjunction with the Academy of Medicine of New Jersey, will present Dr. George Piness, Los Angeles, in a lecture "Allergy in General Practice" at the academy, 91 Lincoln Park, Newark.

Hearing and Speech Center.—The Newark Eye and Ear Infirmary, 77 Central Ave., Newark, announces the opening of the Henry C. Barkhorn Memorial Hearing and Speech Center. Services such as the diagnosis of hearing difficulties, fitting and prescription of hearing aids, and special evaluation and correction are available. Physicians who wish to refer patients may obtain details by writing to the infirmary.

NEW YORK

Society News.—At a meeting of the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn, Oct. 20, 8:45 p. m., MacNaughton Auditorium, the Hon. Samuel S. Leibowitz, judge, Kings County, will have as his topic "The Doctor Testifies." The meeting will open with the inaugural address of Dr. Alfred P. Ingegno, president, Medical Society of the County of Kings, whose topic will be "Medical Care Plans and Medical Snare Plans."——At its annual meeting the Medical Society of the County of New York presented its first distinguished service citations to Drs. Madge C. L. McGuinness and J. Homer Cudmore, New York, for their long and distinguished activities within the councils of the society. The citations are granted with the approval of the Comitia Minora and can be awarded not only to members of the society but to other distinguished physicians, scientists, or persons for notable contributions to the profession of medicine.

New York City

Harvey Lecture.—Hans H. Weber, professor of physiology and director of the Physiological Institute, University of Tübingen, Germany, will deliver the Harvey lecture, "Adenosinetriphosphate and Motility of Living Systems," at the New York Academy of Medicine, Oct. 15.

Symposium on Cardiac Rehabilitation.—A symposium, entitled "Rehabilitation in the Cardiac," will be presented by the New York Society for Circulatory Diseases at its meeting, Oct. 13, 8:30 p. m., in room 440, New York Academy of Medicine building. Dr. Simon Dack will preside. Guest speakers will include Drs. Samuel Kahn, Herman J. Bennett, Irvin Klein, and Abraham Jezer. Members of the medical profession are invited.

Personal.—Dr. Harold Brandaleone, medical director of the Third Avenue Transit System, presented a paper, "Medical Aspects of Accident Prevention" before the Ohio State Safety Conference in Cleveland, Sept. 15.——The Metropolitan Life Insurance Company, which has announced its decision to merge its occupational health and safety services under a new unit known as the Safety and Occupational Health Bureau, has appointed Dr. William J. McConnell, assistant medical director of the company, as director of the bureau.

Columbia-Presbyterian Silver Anniversary.—The Columbia-Presbyterian Medical Center will celebrate its 25th anniversary, Oct. 12-13. The center includes the Babies Hospital, the Institute of Ophthalmology, the Neurological Institute, the New York Orthopedic Dispensary and Hospital, the Presbyterian Hospital, Harkness Pavilion, Sloane Hospital for Women, Squier Urological Clinic and Vanderbilt Clinic, and the Mary

Harkness Convalescent Home at Port Chester, N. Y. (units of Presbyterian), and the school of medicine, school of dental and oral surgery, school of nursing and the school of public health (units of Columbia University), as well as Bard Hall, residence for medical students, Anna C. Maxwell Hall, student nurse residence, and Harkness Memorial Hall, apartment residence for graduate nurses. Affiliated units of the center include two municipal institutions, the Francis Delafield Hospital and the Washington Heights Health and Teaching Center, and one state institution, the Psychiatric Hospital and Institute. (See The Journal, April 11, 1953, page 1295.) There will be papers, Monday morning, by Dr. Hugh R. Leavell, professor of public health practice, Harvard University, Boston, Dr. Joseph L. Lilienthal Jr., professor of experimental medicine, Johns Hopkins University, Baltimore, Dr. William C. Stadie, John Herr Musser professor of research medicine, University of Pennsylvania, Philadelphia, and Dr. A. Ashley Weech, professor of pediatrics, University of Cincinnati. The afternoon session will be devoted to eight concurrent symposiums. Alumni association cocktail parties will be given Monday evening at the Waldorf Astoria Hotel, and the Columbia-Presbyterian Medical Center banquet will be held in the hotel ballroom, where a panel will discuss "Responsibilities and Opportunities of the Medical Center in the Next 25 Years." Tuesday morning the following presentations will be made:

Progress in Cancer Research, Alfred A. Gellhorn, director, Institute for Cancer Research.

Role of the Internist in Medicine Tomorrow, Robert F. Loeb, executive officer, department of medicine.

Study of Human Reproduction, Howard C. Taylor Jr., executive officer, department of obstetrics and gynecology.

New Direction in Surgery, George H. Humphreys II, executive officer, department of surgery.

Honorary degrees and distinguished service awards will be presented during the academic convocation in the hospital garden, 2:30 p. m.

NORTH CAROLINA

Personal.—Dr. Edmond L. Rice, Gastonia, has gone to Lahore, Pakistan, where he will serve as medical missionary of the Methodist Church. Dr. Rice served as a medical missionary in China from 1934 to 1947, except for the war years, when he was surgeon of the Hugh Chatham Memorial Hospital in Elkin.

Symposium on the Kidney.—The Raleigh Academy of Medicine will hold its fifth annual medical and surgical symposium, Oct. 16, at the Hotel Sir Walter in Raleigh. The following symposium on the kidney will be presented:

Franklin A. Kyser, Chicago, Preservation of Renal Function.

Charles P. Barnett, New York, Renal Disease in Children.

Willoughby E. Kittredge Jr., New Orleans, Role of Infection and Obstruction in Renal Disease.

B. Vincent Hall, Ph.D., Urbana, Ill., Renal Filtration and the Ultramicroscope Structure of the Glomerulus.

Joseph F. A. McManus, Birmingham, Ala., Pathological Physiology of Renal Disease.

Homer W. Smith, Sc.D., New York, Historical Perspective in Renal Physiology.

The symposium has been approved by the American Academy of General Practice for postgraduate training credit. There is no registration fee, and all physicians of the state are cordially invited to attend the symposium and the academy dinner, as guests. Registration begins at 9 a. m., with the first speaker at 10 a. m.

OHIO

Personal.—On his 70th birthday, Dr. Carl J. Wiggers, honorary professor of physiology at Frank E. Bunts Educational Institute associated with the Cleveland Clinic, received the degree doctor of medicine honoris causa from the medical faculty of the Ludwig Maximilian University at Munich, Germany, where, in 1912, he had been a pupil of Otto Frank in the physiological institute.——Dr. David W. Heusinkveld, Cincinnati, councilor of the first district, Ohio State Medical Association, has been elected president of the Ohio Tuberculosis and Health Association.——Dr. Marion A. Blankenhorn, professor of medicine, University of Cincinnati College of Medicine, who attended the Youngstown Hospital Association, August 17-19, conducted ward rounds, clinical conferences, and meetings for the house and visiting staffs and gave a formal evening lecture under the sponsorship of the medical staff of the hospital.

Northwestern Ohio Medical Meeting.—The 109th assembly of the Northwestern Ohio Medical Association will be held at the Academy of Medicine, Toledo, Oct. 14. After an address of welcome by Dr. Wendell W. Green, president of the Toledo and Lucas County Academy of Medicine, the following program will be presented:

H. Keith Fischer, Philadelphia, Psychiatry and the Physician's Responsibility in Teen Age Development and in the Problems of Young Adults.

Charles P. Bailey, Philadelphia, Advances in Cardiac Surgery.

Ernest M. Brown Jr., Philadelphia, Uses and Abuses of ACTH and Cortisone Therapy.

Informal round-table conferences with guest speakers will be held during luncheon, 12:20-1:30 p. m. Afternoon presentations will include "Ovarian Cancer" by Dr. Craig W. Muckle, Philadelphia, and "Advances in Pediatric Surgery" by Dr. H. William Clatworthy, Columbus. The registration fee, $10, for all members and nonmembers includes cost and noon dinner. Reservations may be made through Dr. Henry B. Larzelere, Program Chairman, Northwestern Ohio Medical Association, 1838 Parkwood Ave., Toledo 10.

OREGON

University News.—At the University of Oregon Medical School, Portland, Dr. Harry G. Beckwith Jr., Wheeler, has been appointed visiting clinical instructor in surgery; Dr. Lowell W. Keizur, Longview, Wash., clinical instructor in urology; and Dr. Nathaniel D. Wilson, Portland, clinical instructor in surgery.——Dr. Thomas E. Talbot, assistant professor of ophthalmology, University of Oregon Medical School, Portland, and for the past two years supervisor of the children's eye clinic, has resigned to enter private practice. He will be replaced by Dr. John P. Keizer, who will hold the academic rank of instructor.——The Oregon State Elks Association recently contributed $10,162 in continuing support of its program to aid visually handicapped children. The funds will be administered under the direction of Dr. Kenneth C. Swan, head of the department of ophthalmology, University of Oregon Medical School, Portland.

State Medical Meeting at Portland.—The 79th annual session of the Oregon State Medical Society will convene at the Masonic Temple in Portland, Oct. 14-17, under the presidency of Dr. John D. Rankin, Coquille. All members of the society are invited to attend the daily 7 o'clock breakfast meetings of the house of delegates in the Georgian Room, Hotel Heathman. The Sommer Memorial Lectures will be delivered by Dr. Russell L. Cecil, New York, ("The Treatment of Chronic Arthritis," "Old Age and the Vices," and "Influenza and the Common Cold"); Dr. Arthur P. Stout, New York, ("Relation of Benign Breast Lesions to Cancer," "Tumors of Soft Tissues," and "Early Diagnosis of Carcinoma of the Prostate"); and Dr. Philip D. Wilson, New York, ("Stress Reactions Following Operations on the Bones and Joints," "An Evaluation of the Bone Bank After Six Years' Experience and Follow-Up," and "Low Back Pain and Sciatica"). Clinical pathological conferences will be held at 3:30 p. m. Wednesday and 11 a. m. Thursday. There will be a panel discussion, "The Management of Important Fluid and Electrolyte Disturbances in Medical and Surgical Patients," at 2 p. m. Wednesday. The social hour in the Emerald Room of the Hotel Multnomah will precede the annual banquet in the grand ballroom, 7 p. m., which will be addressed by Alfred K. Schwette, Seattle, chairman, Committee on Peace and Law, American Bar Association. The annual Oregon medical golf tournament will be held at the Portland Golf Club, Saturday, 7:30 a. m. There will be a football game between the University of Oregon and the University of Washington at Multnomah Civic Stadium, 1:30 p. m.

PENNSYLVANIA

Society News.—At a recent meeting, Dr. Albert A. Martucci, Philadelphia, was elected president of the Pennsylvania Academy of Physical Medicine and Rehabilitation; Dr. Francis J. Bonner, Ardmore, vice-president; and Dr. J. Murl Johnston, Pittsburgh, secretary-treasurer.

Seminar on Physical Medicine.—The Pennsylvania Academy of Physical Medicine and Rehabilitation and the New Jersey Society of Physical Medicine will hold a joint seminar on physical medicine and rehabilitation, Oct. 17, 1:30 p. m., at Sacred Heart Hospital, Allentown. The following papers will be presented:

Rehabilitation of Injuries of the Hand, Harry Miller, Allentown.
Recent Advances in Arthritis, Richard T. Smith, Philadelphia.
Peripheral Vascu'ar Disease, Bruce R. Marger, Quakertown.
Hemiplegia, J. Murl Johnston, Pittsburgh.
Shoulder, William H. Schmidt, Philadelphia.
Poliomyelitis, George J. Boines, Wilmington, Del.

Dinner at the American Hotel will be followed at 8:15 p. m. by a symposium on low back pain, with Dr. Dominic A. Donio, Allentown, moderator. Physicians, therapists, nurses, and students are cordially invited to attend. Dinner is $5 per person; there is no fee for the seminar.

Philadelphia

Lectures on Medical History.—The Section on Medical History of the College of Physicians of Philadelphia announces six weekly lectures on medical history for students of all Philadelphia medical schools at the Hall of the College of Physicians, 19 So. 22nd St., on Monday evenings, 7-8 p. m., beginning Oct. 12. The course covers an introduction on the meaning and values of medical history, classical and medieval medicine, renaissance medicine, medicine during the 17th, 18th, 19th, and 20th centuries, and the social aspects of medical history. Supported by the five medical schools of Philadelphia, the course will be conducted by Richard H. Shryock, Ph.D., and Dr. Owsei Temkin, both of the Institute of the History of Medicine at Johns Hopkins University School of Medicine, Baltimore.

TENNESSEE

Public Medical Forums.—The Public Service Committee of the Nashville Academy of Medicine and the Nashville *Banner* are sponsoring public medical forums during October and November. The forums will be held in three large Nashville high school auditoriums and in the War Memorial Building. Subjects to be discussed by members are: "Nutrition and Overweight," "Cancer," "The Overuse and Abuse of Drugs," and "Accidents to Children."

Civil Defense Course.—An eight hour civil defense lecture course, "Standard Emergency Treatment of Atomic Bomb Injuries," is being offered to Tennessee physicians under the sponsorship of the Tennessee State Medical Association. The West Tennessee schedule, which initiates the course, began in Union City, Oct. 7. The remainder of the West Tennessee schedule for October (all lectures at 4 p. m.) is as follows: Union City, Oct. 14, First Christian Church; Ripley, Oct. 14 and Oct. 21, First Christian Church; Jackson, Oct. 21 and Oct. 28, Jackson-Madison County General Hospital.

Society News.—The following groups recently elected officers: Tennessee Academy of Ophthalmology and Otolaryngology: president, Dr. Clyde R. Kirk, Chattanooga; vice-president, Dr. Charles M. King, Memphis; secretary-treasurer, Dr. John T. Bryan, Nashville.——Tennessee State Pediatric Society: president, Dr. Amos Christie, Nashville; vice-president, Dr. Luke L. Ellenburg, Greeneville; secretary-treasurer, Dr. Philip C. Elliott, Nashville.——Tennessee Academy of General Practice: president, Dr. Louis A. Killeffer, Harriman; president-elect, Dr. Ben L. Pentecost, Memphis; vice-presidents, Drs. Rae B. Gibson, Greeneville, J. Fred Terry, Cookeville, and John A. McQuiston, Memphis; secretary-treasurer, Dr. Daniel J. Johns, Nashville.——The Tennessee Thoracic Society: Dr. David H. Waterman, Knoxville, president; Dr. Duane M. Carr, Memphis, vice-president; and Dr. Hollis E. Johnson, Nashville, secretary-treasurer.

GENERAL

Meeting of American Fracture Association.—The annual meeting of the American Fracture Association will be held at the Mission Inn, Riverside, Calif., Oct. 12-15. Guest speakers will be Dr. Earl D. McBride, Oklahoma City, and Dr. Juan Faril, Mexico City, Mexico. A feature of the meeting will be a round-table discussion on prosthetic replacements in hip fractures and allied conditions.

Occupational Accidents.—According to the 1953 edition of the National Safety Council's statistical annual, "Accident Facts," 15,000 persons were killed and 2,000,000 injured while at work in 1952. The total time lost as a result of occupational injuries was 250 million man-days, and the cost to American industry was $45 per worker. Detailed statistical information is provided on motor vehicle, transportation, home, farm, and school accidents. Single copies of the book may be obtained from the National Safety Council, 425 N. Michigan Ave., Chicago 11, at 75 cents. Prices are reduced for quantities.

Rockefeller Foundation Report.—According to the annual report of the Rockefeller Foundation, a total of $16,640,355 was appropriated in 1952, and of this amount $3,599,698 was applied to work in medicine and public health. Of the latter amount, $275,000 was set aside for 1953 virus investigations carried out by the foundation staff members, and $728,258 was allocated for field service expenses in 1953. For its fellowship activities in 1952, the foundation made available a total of $1,050,000. To advance this program in 1953 the sum of $1,025,000 was allocated for use by the several divisions as follows: medicine and public health, $400,000; natural sciences and agriculture, $300,000; social sciences, $175,000; and humanities, $150,000.

Anesthesiologists Meet in Boston.—The New England Society of Anesthesiologists and the Massachusetts Society of Anesthesiologists will hold a combined meeting, Oct. 16, at Joslin Auditorium of the New England Deaconess Hospital, Boston. The forenoon is reserved for clinics. In the afternoon the following program will be presented:

Anesthesia Mortality Committee: Presentation of Cases, Jacob H. Fine, Chairman, Beverly, Mass.
Anesthesia for the Acutely Burned Patient, John Bunker, Boston.
Anesthesia for Surgery of the Acute Abdomen, Arthur E. Ogden, Boston.

Guest speaker at the evening scientific program will be Dr. Enrico Ciocatto, professor of anesthesiology at the University of Turin, Italy. Physicians and medical students are invited.

Fund for Teachers and Investigators.—The John and Mary R. Markle Foundation will continue for a seventh year the Scholar in Medical Science program to help scientists on medical school faculties to become established as teachers and investigators in their chosen fields. A total of 111 scholars on the staffs of 55 medical schools in the United States and Canada have been aided by these grants since the program began. Each medical school is invited to nominate one faculty member as a candidate for the five year, $30,000 grant. For support of each scholar selected, the medical school receives an annual grant of $6,000 for the term of the appointment. All nominations should be in the foundation offices on or before Dec. 1. A booklet giving further information may be obtained from the foundation, 14 Wall St., New York 5.

International Union of the Physiological Sciences.—During the meeting of the International Physiological Congress in Montreal, Canada, official delegates from physiological societies of 17 countries voted unanimously to form the International Union of the Physiological Sciences. A council of 11 members was elected, with Dr. Charles H. Best, Toronto, as president and Dr. Maurice B. Visscher, Minneapolis, as secretary for three year terms. The council was instructed by the assembly of the I. U. P. S. to complete arrangements for adherence to the International Council of Scientific Unions and the Council for International Organizations in the Medical Sciences and to initiate actions looking toward improvements in the abstracting and indexing of literature in the physiological sciences on a world basis.

Fiftieth Anniversary Issue.—The July issue of *The Journal of Bone and Joint Surgery* is the 50th anniversary issue. The publication, which originally appeared under the name of the *American Journal of Orthopedic Surgery*, was subsequently named the *Journal of Orthopedic Surgery* when it became the official publication of the British Orthopedic Association, formed at the close of World War I. In 1922 the present title was adopted; in 1935 the journal, which had hitherto been the official publication of the American and the British journals of orthopedic surgery, became the official organ of the American Academy of Orthopedic Surgeons, and in 1950, of the American Society for Surgery of the Hand. In 1948 the journal was divided into volume A, representative of American orthopedic surgery, and volume B, representative of British orthopedic surgery, each complementing the other and each published by the orthopedic surgeons of the respective country.

Accidents Among Teen-Agers.—According to the Metropolitan Life Insurance Company, accidents constitute the greatest threat to teen-agers. A study of experience among industrial policyholders of the company shows that between ages 13 and 19 the death rate among boys rises from 0.64 to 1.31 per 1,000 but among girls from 0.37 to only 0.56 per 1,000. In 1950-1952 the death rate from accidents for girls doubled from ages 13-14 to 18-19 years, when it reached 14.7 per 100,000; the death rate for boys almost tripled over the same age range, reaching a level of 85.7 per 100,000 at 18-19. Motor vehicle accidents, the leading cause of accidental death among teen-agers, increase rapidly in relative importance during this period. At ages 18-19, they accounted for almost two-thirds of all accidental deaths among boys and about four-fifths of those among girls. Among teen-age boys, drowning ranked second as a cause of accidental death, with firearms third and occupational accidents fourth.

Fellowships in Tuberculosis Research.—The American Trudeau Society annually provides a limited number of fellowships to promote the training and development of investigators in the field of tuberculosis and related pulmonary diseases. The awards are open to citizens of the United States for work within this country. Preference is given to candidates not more than 30 years of age who have the degree of doctor of medicine or other doctoral degree. Within the field of research on tuberculosis, applications will be considered in the special disciplines of clinical medicine and surgery, epidemiology, chemistry, microbiology, pathology, and pulmonary physiology. Stipends may vary from $3,000 to $3,600 per annum. No other remunerative work will be permitted during the tenure of the fellowship. Appointments are made for one year but may be renewed up to three years. Details may be obtained from the Director of Medical Research, American Trudeau Society, % Henry Phipps Institute, Seventh and Lombard Streets, Philadelphia 47.

Grants for Muscular Dystrophy Research.—The Muscular Dystrophy Associations of America, Inc., 39 Broadway, New York, announces four grants, the largest of which will be used for expansion of the muscular dystrophy research program at New York Hospital, under the supervision of Dr. Ade T. Milhorat. It includes studies involving a metabolism ward, dietary kitchen, extensive laboratory facilities, and a staff of investigators and technicians. The program will be expanded at a yearly increase of $44,000 to a total annual cost of $105,495. The other grants are (1) to Dr. Archibald R. Buchanan and Verne van Breeman, University of Colorado, Denver, $7,722 for "Electron Microscope Studies of Neuromuscular Relationships under Normal and Pathologic Conditions"; (2) to Dr. Georges Schapira, Laboratoire de Recherches de Biochimie Medicale, Paris, France, $6,500 for continuation of studies on "Biochemistry of Muscle in Progressive Muscular Dystrophy"; and (3) to Dr. Kenneth L. Zierler, Johns Hopkins Hospital, Baltimore, $4,050 for continuation of studies on "The Relation of Vitamin E to Glycolysis in Skeletal Muscle."

Noise Abatement Symposium.—The national noise abatement symposium will be held at the Armour Research Foundation of Illinois Institute of Technology (35 W. 33rd St., Chicago), Oct. 23-24, under the joint sponsorship of the A. M. A. Council on Industrial Health, Acoustical Materials Association, Acoustical Society of America, American Industrial Hygiene Association, American Institute of Architects, American Society of Planning Officials, American Society of Safety Engineers, Armour Research Foundation of Illinois Institute of Technology, and the National Noise Abatement Council. Friday and Saturday mornings will be devoted to discussions on outdoor noise. The Friday luncheon meeting, 12:15-1:45 p. m., will be addressed by C. A. Armour, vice-mayor and commissioner of police and fire, Memphis, Tenn., whose topic will be "Noise Abatement, Memphis Style." Under the general topic, "The Noise Hazard Situation," the following topics will be considered Friday afternoon: "The Relation of Hearing Losses to the Noise Exposure in Industry," "Recent Noise Hazard Legislation and Its Implications," and "Combating the Effects of Noise." The Saturday luncheon meeting will be addressed by Vern O. Knudsen, Ph.D., University of California, Los Angeles, whose topic will be "Noise and Culture."

Society News.—**The American Congress of Physical Medicine and Rehabilitation** has elected Dr. William B. Snow, New York, president; Dr. William D. Paul, Iowa City, president-elect; Dr. Frances Baker, San Mateo, Calif., secretary; and Dr. Frank H. Krusen, Rochester, Minn., treasurer. Vice-presidents are Drs. Howard A. Rusk, New York, Gordon M. Martin, Rochester, Minn., Alvin B. C. Knudson, Washington, D. C., Donald L. Rose, Kansas City, Kan., and Arthur C. Jones, Portland, Ore. Dr. Walter J. Zeiter, Cleveland, is executive director, and Dorothea C. Augustin, Chicago, is executive secretary.——**Carbon Dioxide Research Association** was recently incorporated under the laws of the state of New York to succeed the Committee on Carbon Dioxide Research. The officers of the association are Dr. Albert A. LaVerne, New York, president; Drs. Ladislas J. Meduna, Chicago, and Robert B. McGraw, New York, vice-presidents; Dr. Abraham I. Jackman, Chicago, corresponding secretary; Dr. John D. Moriarty, Los Angeles, recording secretary; and Dr. Robert E. Peck, New York, treasurer. Physicians who desire to become members or who are interested in obtaining information relative to the use of carbon dioxide therapy in psychiatry should contact the corresponding secretary. Membership fee, $5.

Clinical Pathologists Meet in Chicago.—The American Society of Clinical Pathologists will hold its 32nd annual meeting and 19th seminar at the Drake Hotel, Chicago, Oct. 13-16 under the presidency of Dr. Henry F. Hunt, Danville, Pa. The sessions will open Tuesday, 9 a. m., with a symposium on blood bank methodology under the joint sponsorship of the American Society of Clinical Pathologists and the College of American Pathologists. Dr. Donald H. Kaump, Detroit, will serve as moderator. The all day symposium will terminate with the presentation at 4:30 p. m. of "Indications and Contraindications for Whole Blood and Its Various Fractions" by the guest speaker, Dr. Israel Davidsohn, Chicago, immediate past president of the society. A reception and fellowship hour in the grand ballroom will precede the annual banquet, 7 p. m., in the Gold Coast room, which will be held jointly with the College of American Pathologists. The presidential address, "A Principle Worth Fighting for," will be delivered during the Wednesday morning session, immediately preceding a round-table luncheon in the Gold Coast room, sponsored jointly by the society and the college (admission by ticket only). Wednesday, 2 p. m., Dr. Edwin F. Hirsch, Chicago, will moderate a symposium on surgical pathology. On Thursday morning, by special invitation of the program committee, Dr. William F. Scherer and Dr. Jerome T. Syverton, Minneapolis, will present "The Use of Tissue Culture in the Propagation of Viruses," and Dr. Joseph F. McManus, Birmingham, Ala., will speak on practical connective tissue histochemical techniques. In the afternoon, by special invitation, Dr. Thomas H. McGavack and Sidney Pearson, New York, will discuss "The Chemical Determination of Urinary Steroids." Friday Dr. Lauren V. Ackerman, St. Louis, will be moderator for an all day seminar, "Diseases of the Skeleton, Including Neoplasms."

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

Area	Sept. 26, 1953 Paralytic Type	Sept. 26, 1953 Total Cases Reported	Sept. 27, 1952 Total

Formation of an American Association of Public Health Physicians.—On Nov. 29, 1951, several state and territorial health officers, while attending the annual meeting of the Association of State and Territorial Health Officers, met unofficially and discussed the need for an American Association of Public Health Physicians. A committee was appointed, and after several meetings with other groups it has scheduled a meeting of its own which is to be held at 8:30 p. m., Nov. 9 at the Hotel Statler, New York. The meeting will coincide with the meeting of the American Public Health Association, and all doctors of medicine engaged in full-time public health activities are invited to attend. A full and free discussion is desired to map plans for the formation of an American Association of Public Health Physicians, if such should be wanted. Such an association has been proposed with aims and objectives as follows:

1. To provide a greater degree of leadership at the national level on the part of all public health physicians in the field of public health in the interest of better health for the people of the United States and her territories.
2. To promote legislation and to influence public opinion at the national level in the presentation of the aims and objectives of departments of health at all levels of government.
3. To represent public health physicians at the national level in their relationships with other national associations and groups.
4. To work for improved practices in the field of public health administration from the viewpoint of the public health physician.
5. To serve as a liaison group between the American Medical Association and the American Public Health Association in an effort to bring both groups closer together in the public interest.
6. To be interested in and to promote the best interests of public health physicians.

The association would be interested primarily in carrying on business matters rather than in scientific programs. According to those interested in this new association the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association and the American Public Health Association, as well as other national, state, and local scientific meetings, should be attended and supported by public health physicians. They believe they can strengthen these groups and that the latter are adequate to provide the scientific programs needed at the national level. The membership would be limited to those doctors of medicine who are engaged in full-time public health work in the United States or her territories. The usual officers would be provided for, including possibly a full or part-time lay executive secretary. The governing body would be a house of delegates, which would elect the officers and determine the broad policies of the association. A board of trustees would govern the association between meetings of the house of delegates. Major policy decisions would be made by referendums when desired or indicated. The annual meeting would consist principally of a meeting of the house of delegates, which might be held at the same time as the annual meeting of the American Public Health Association. The association would be supported by annual dues not to exceed $5, plus contributions from other associations, individual companies, and contributing sponsors. The active members of the association in any state or territory could organize local, affiliated branch organizations as desired. The active members of the association in each state and territory would be allowed to send delegates to the annual meeting of the house of delegates in proportion to the number of active members in each state and territory.

CANADA

Refresher Course for General Practitioners.—The Royal Victoria Hospital, Montreal, will conduct a course for general practitioners, Nov. 23-28, covering those conditions most commonly encountered in general practice, with emphasis on practical office procedures used in medicine, surgery, obstetrics and gynecology, and psychiatry. Fee for the course, which is limited to 50 applicants, is $50. For details address the Post-Graduate Board, Royal Victoria Hospital, 687 Pine Ave. West, Montreal.

CORRECTION

Treatment of Epilepsy.—Dr. Elinor R. Ives writes that in the article "Results of Intensive (Narcosis) and Standard Medical Treatment of Epilepsy," in The Journal, Aug. 8, 1953, in the columns in which figures are given from Dr. Ives' article on epilepsy, published in The Journal, Dec. 1, 1951, page 1332, the following errors occurred:

For phenobarbital, under grade 3 of improvement, the figure 19 should be added.

For diphenylhydantoin, the figure 20 under 0 improvement should be 22.

For Mesantoin, the figure 39 should be 10, the figure 12 should be 29, and the figure 20 should be 22.

For trimethadione, the figure 23 should be 29.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy for Cerebral Palsy, Western Hills Hotel, Fort Worth, Texas, Oct 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Ophthalmology and Otolaryngology, Palmer House, Chicago, Oct. 12-16. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Executive Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Association of Blood Banks, LaSalle Hotel, Chicago, Oct. 17-20. Miss Marjorie Saunders, 3500 Gaston Ave., Dallas 4, Texas, Secretary.

American Cancer Society, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Cardiology, Hotel Statler, Cleveland, Ohio, Nov. 6-7. Dr. Philip Reichert, 480 Park Ave., New York 22, Secretary.

American Fracture Association, Mission Inn, Riverside, Calif., Oct. 12-15. Dr. H. W Wellmerling, 120 S. LaSalle St., Chicago 3, Secretary.

American Otorhinologic Society for Plastic Surgery, Morrison Hotel, Chicago, Oct. 11. Dr. Louis J. Feit, 66 Park Ave., New York, Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Clinical Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Clyde G. Culbertson, 1040 W. Michigan St., Indianapolis, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Knickerbocker, Chicago, Nov. 1-2. Dr. O. J. Pollak, P. O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, Hotel Claridge, Atlantic City, N. J., Oct. 26-28. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Life Insurance Medical Directors of America, Hotel Statler, New York, Oct. 14-16. Dr. Henry B. Kirkland, P. O. Box 594, Newark 1, N. J., Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Association of State and Territorial Health Officers, Washington Hotel, Washington, D. C., Nov. 4-7. Dr. John D. Porterfield, 306 Ohio Depts. Bldg., Columbus 15, Ohio, Secretary.

Central Association of Obstetricians and Gynecologists, The Shamrock, Houston, Texas, Nov. 5-7. Dr. Harold L. Gainey, Suite 602, 116 South Michigan Ave., Chicago 3, Secretary.

Central Neuropsychiatric Association, Claypool Hotel, Indianapolis, Oct. 15-17. Dr. Hamilton Ford, 112 North Blvd., Galveston, Texas, Secretary.

Conference of Public Health Veterinarians, Hotel New Yorker, New York, Nov. 9. Dr. James Lieberman, U. S. Public Health Service, Washington 25, D. C., Secretary.

College of American Pathologists, Drake Hotel, Chicago, Oct. 12-16. Dr. Harry P. Smith, 203 N. Wabash Ave., Chicago 1, Secretary.

Congress of Neurological Surgeons, Roosevelt Hotel, New Orleans, Nov. 12-14. Dr. B. W. Cannon, 1092 Madison Ave., Memphis, Tenn., Secretary.

Constantinian Society, Battery Park Hotel, Asheville, N. C., Oct. 18-21. Dr. C. F. Shook, Medical Director, Owens-Illinois Glass Company, Toledo 1, Ohio, Secretary.

Delaware, Medical Society of, Hotel du Pont, Wilmington, Oct. 12-14 Dr. Andrew M. Gehret, 822 North American Bldg., Secretary.

Gulf Coast Clinical Society, Admiral Semmes Hotel, Mobile, Ala., Oct. 15-16. Dr. William J. Atkinson Jr., 1217 Government St., Mobile 20, Ala., Secretary.

Indiana State Medical Association, French Lick, Oct. 19-21. Mr. James A. Waggener, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

Interstate Post Graduate Medical Association of North America, Palmer House, Chicago, Nov. 2-5. Dr. E. R. Schmidt, 1300 University Ave., Madison 5, Wisconsin, Secretary.

Inter-Society Cytology Council, Philadelphia, Nov. 19-20. Dr. Paul F. Fletcher, 634 North Grand Blvd., St. Louis 3, Secretary.

Midwestern Section of American Federation for Clinical Research, Congress Hotel, Chicago, Oct. 29. Dr. Robert J. Glaser, 600 S. Kingshighway Blvd., St. Louis 10, Secretary.

National Association for Mental Health, New York, Nov. 17-19. Dr. George S. Stevenson, 1790 Broadway, New York 19, Medical Director.

National Gastroenterological Association, Hotel Biltmore, Los Angeles, Oct. 12-17. Dr. A. Xerxes Rossien, 1819 Broadway, New York 23, Secretary.

National Proctologic Association, Congress Hotel, Chicago, Oct. 15-17. Dr. George E. Mueller, 59 East Madison St., Chicago 2, Secretary.

National Society for Crippled Children and Adults, Palmer House, Chicago, Nov. 12-14. Mr. Lawrence J. Linck, 11 South LaSalle St., Chicago 3, Secretary.

New England Obstetrical and Gynecological Society, Hotel Somerset, Boston, Oct. 28. Dr. Carmi R. Alden, 270 Commonwealth Ave., Boston, Secretary.

North Pacific Surgical Association, Victoria, B. C., Nov. 20-21. Dr. John A. Duncan, 509 Olive Way, Seattle, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Oct. 26-29. Miss Alma F. O'Donnell, 512 Medical Arts Bldg., Oklahoma City 2, Executive Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 26-30. Miss Irene Rau, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Oregon State Medical Society, Heathman Hotel, Portland, Oct. 14-17. Dr. Charles E. Littlehales, 833 S.W. Eleventh Ave., Portland 5, Secretary.

Regional Meetings, American College of Physicians:

Michigan, H. H. Rackham Auditorium, Ann Arbor, Dec. 5. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Governor.

Midwest—Ill., Ind., Iowa, Minn., Wis.—Hotel Schroeder, Milwaukee, Nov. 21. Dr. Francis D. Murphy, 536 West Wisconsin Ave., Milwaukee 3, Chairman.

New England—Conn., Maine, Mass., N. H., R. I., Vt.—Hartford, Conn., Oct. 28. Dr. John C. Leonard, 80 Seymour St., Hartford 15, Conn., Chairman.

New Jersey, Trenton, Nov. 4. Dr. Edward C. Klein Jr., 73 Lincoln Park, Newark 2, Governor.

North Carolina, Chapel Hill, Dec. 3. Dr. Elbert L. Persons, Duke Hospital, Durham, Governor.

Southeastern—Cuba, Alabama, Florida, Georgia, South Carolina—St. Simons, Sea Island, Ga., Oct. 16-17. Dr. Carter Smith, 384 Peachtree St. N.E., Atlanta 3, Ga., Chairman.

Jones, Everett Orville ⊕ Seattle; University of Pennsylvania School of Medicine, Philadelphia, 1893; an Associate Fellow of the American Medical Association; member of the North Pacific Surgical Association; fellow of the American College of Surgeons; affiliated with Providence and Swedish hospitals; died in Saratoga, Calif., Aug. 5, aged 81, of carcinoma of the prostate.

Kaveney, Joseph James ⊕ Captain, U. S. Navy, retired, Washington, D. C.; Georgetown University School of Medicine, Washington, D. C., 1904; entered the U. S. Navy April 23, 1921, and retired Jan. 1, 1943; died Aug. 25, aged 73, of coronary occlusion.

Keskey, George Isaac ⊕ Marquette, Mich.; University of Michigan Medical School, Ann Arbor, 1922; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; on the staff of St. Mary's and St. Luke's hospitals; died Aug. 14, aged 56, of coronary thrombosis.

Klapproth, Herman ⊕ Sherman, Texas; University of Texas School of Medicine, Galveston, 1929; specialist certified by the American Board of Radiology; member of the American College of Radiology; past president of the Texas Radiological Society; in 1947 president of the Grayson County Medical Society; affiliated with St. Vincent's and Wilson N. Jones hospitals; died in Midland April 3, aged 49, of a heart attack.

Kleinman, Maurice ⊕ Newark, N. J.; University and Bellevue Hospital Medical College, New York, 1927; served during World War II; civilian ophthalmologist at the Newark Armed Forces Induction Station, 1942-1943, for which he received a commendation certificate; served in the prevention department with the mobile eye clinic of the New Jersey Commission for the Blind; died Sept. 1, aged 52, as the result of a fall.

Knox, John ⊕ Lumberton, N. C.; University of Maryland School of Medicine, Baltimore, 1906; past president of the Robeson County Medical Society; died June 25, aged 70, of acute coronary thrombosis.

Lomax, Claude Carl ⊕ Costa Mesa, Calif.; Louisville and Hospital Medical College, Louisville, Ky., 1908; member of the Indiana State Medical Association; for two terms health officer of Spencer County, Ind.; died July 14, aged 69, of cardiovascular renal disease.

London, Stephen ⊕ New York City; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1913; assistant clinical professor of medicine, New York Medical College, Flower and Fifth Avenue Hospitals; on the staff of the New York Polyclinic Medical School and Hospital; died Aug. 23, aged 67, of coronary thrombosis.

Long, Samuel Calvin, Bakersfield, Calif.; Hahnemann Hospital College of San Francisco, 1901; served as examiner of the state lunacy commission for Kern County, school physician, and county health officer; died Aug. 19, aged 83.

Love, George Robert ⊕ Oconomowoc, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1922; first president of the Wisconsin State Medical Golfers' Association; medical director of the Summit Hospital, where he died May 26, aged 55, of acute myocardial failure.

McGinley, Charles ⊕ Lynn, Mass.; Baltimore Medical College, 1904; affiliated with Lynn Hospital and Union Hospital; died July 29, aged 74, of cancer.

McKee, Robert Morrow ⊕ Beaver, Pa.; University of Pittsburgh School of Medicine, 1941; specialist certified by the American Board of Dermatology and Syphilology; served during World War II; instructor in dermatology at his alma mater; on the staffs of the Providence Hospital in Beaver Falls, Beaver Valley General Hospital in New Brighton, and Rochester (Pa.) General Hospital, where he died July 28, aged 38.

Masilko, Vandy Frank ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; an Associate Fellow of the American Medical Association; served on the staff of St. Anthony de Padua Hospital; died in River Forest, Ill., Aug. 21, aged 86, of cardiac decompensation.

Miley, Levi Emerson, Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; practiced in Chicago for many years; died in the Blodgett Memorial Hospital July 17, aged 101 of chronic prostatism with hemorrhage.

Morley, Grace Clark ⊕ Hoboken, N. J.; New York Medical College and Hospital for Women, Homeopathic, New York, 1914; died July 13, aged 67, of carcinoma of the liver.

Myers, George Thomas ⊕ Norfolk, Va.; Medical College of Virginia, Richmond, 1901; for many years city physician; an honorary member of the visiting staff of Norfolk General Hospital; died July 8, aged 75.

Nalley, Thomas J., Ontario, Calif.; Washington University School of Medicine, St. Louis, 1905; surgeon at the U. S. Army Quartermaster Depot at Mira Loma for many years; died Aug. 2, aged 73, of coronary thrombosis.

Novak, Anna F., Chicago; Bennett Medical College, Chicago, 1895; served on the staff of Women and Children's Hospital; died Aug. 31, aged 89, of cerebral hemorrhage and arteriosclerosis.

Peters, Erwin Emanuel ⊕ Monroe, Wis.; Cornell University Medical College, New York, 1936; specialist certified by the American Board of Internal Medicine; served during World War II; associate preceptor, University of Wisconsin, Madison; at one time on the faculty of his alma mater; died July 6, aged 42, of cerebral vascular accident.

Pitts, Howard, Chicago; Bennett Medical College, Chicago, 1911; died in St. Joseph (Mich.) Memorial Hospital Aug. 13, aged 72, of adenocarcinoma of the prostate with metastases.

Range, William Edgar, Caseyville, Ill.; Barnes Medical College, St. Louis, 1901; health officer; also a graduate pharmacist; affiliated with St. Mary's Hospital in East St. Louis, where he died Aug. 14, aged 80, of arteriosclerotic heart disease.

Roberts, Aaron Lamar ⊕ Fort Worth, Texas; University of Texas School of Medicine, Galveston, 1916; specialist certified by the American Board of Radiology; member of the Radiological Society of North America; past president of the Thirteenth District Medical Society; served overseas during World War I; affiliated with City-County Hospital; died April 8, aged 65, of cerebrovascular accident.

Roberts, John Nunnally ⊕ Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1934; assistant clinical professor of surgery (urology) at his alma mater; served during World War II; formerly deputy county coroner; affiliated with St. Vincent Infirmary, and Arkansas Baptist, Missouri Pacific, and Veterans Administration hospitals; died Aug. 15, aged 42, of coronary thrombosis.

Robertson, Moorman Owen ⊕ Bedford, Ind.; University of Louisville (Ky.) School of Medicine, 1911; at one time medical missionary in Korea; affiliated with Dunn Memorial Hospital, where he died Aug. 18, aged 66, of injuries received in an automobile accident.

Rossiter, Thomas Jerome ⊕ Washington, D. C.; National University Medical Department, Washington, 1902; died Sept. 2, aged 81.

Sears, Frederick Manning, West Dennis, Mass.; Boston University School of Medicine, 1901; died June 20, aged 76, of coronary thrombosis.

Seitz, Sherwood Bretz ⊕ Barnesville, Minn.; Northwestern University Medical School, Chicago, 1936; certified by the National Board of Medical Examiners; served during World War I; affiliated with St. Ansgar's Hospital in Moorhead; died Aug. 4, aged 53, of coronary occlusion.

Shaham, Simon ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1901; affiliated with Mount Sinai Hospital (Albert Einstein Medical Center-Southern Division); died Aug. 2, aged 77, of acute pulmonary edema.

Shapiro, Lawrence Milton ⊕ New York City; University and Bellevue Hospital Medical College, New York, 1933; specialist certified by the American Board of Pediatrics; fellow of the American Academy of Pediatrics; in 1935 appointed on the medical board of the board of education; affiliated with Bellevue and Beth Israel hospitals; died Aug. 27, aged 45, of coronary sclerosis.

Smith, Henry Greene ⊕ Essex Fells, N. J.; Chattanooga (Tenn.) Medical College, 1909; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served overseas during World War I; for many years affiliated with Essex County Overbrook Hospital in Cedar Grove; died Aug. 3, aged 64, of myocardial failure.

Capt. Joseph J. Engelbreit, M.C., U.S.A.F. (Reserve), 1928-1953

Snow, Frank Simeon, Palatine Bridge, N. Y.; Albany (N. Y.) Medical College, 1889; died June 16, aged 86, of coronary heart disease.

Stone, Gordon ⊕ Cleveland; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1921; died in the City Hospital Aug. 15, aged 55, of coronary thrombosis.

Suer, Robert Eugene ⊕ Wilmington, Ohio; Indiana University School of Medicine, Indianapolis, 1948; served during World War II; county coroner; died Aug. 13, aged 28.

Sullivan, Lawrence Francis ⊕ Donahue, Iowa; State University of Iowa College of Medicine, Iowa City, 1904; died Aug. 10, aged 73, of cerebral arteriosclerosis and coronary artery disease.

Talge, Edward George ⊕ Evanston, Ill.; Northwestern University Medical School, Chicago, 1925; member of the American College of Allergists; formerly on the faculty of his alma mater; past president of the Evanston Branch of the Chicago Medical Society; served as secretary-treasurer and president of the Chicago Society of Allergy; affiliated with St. Francis Hospital and Evanston Hospital, where he died Sept. 7, aged 53, of coronary disease.

Twyeffort, Louis Hollenback ⊕ Bryn Mawr, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1934; specialist certified by the American Board of Psychiatry and Neurology; served on the faculty of his alma mater; member of the American Psychosomatic Society and the American Psychiatric Association; affiliated with the Institute of Pennsylvania Hospital; died in Bedford Village, N. Y., July 30, aged 51.

von Buddenbrock, Erick ⊕ Racine, Wis.; University of Pennsylvania Department of Medicine, Philadelphia, 1905; fellow of the American College of Surgeons; past president of the Racine County Medical Society; affiliated with St. Luke's and St. Mary's hospitals; died May 25, aged 71, of coronary thrombosis.

Walton, Gordon Graham ⊕ Paterson, N. J.; University and Bellevue Hospital Medical College, New York, 1904; for many years assistant city physician; served as health officer of the borough of West Paterson; formerly county coroner; served on the staff of the Paterson General Hospital, where he died Aug. 4, aged 74, of congestive heart failure and arteriosclerotic heart disease.

Weiss, Charles ⊕ Miami Beach, Fla.; University and Bellevue Hospital Medical College, New York, 1915; member of the Medical Society of the State of New York; died July 26, aged 62.

Wellman, Orand Forrest ⊕ San Pedro, Calif.; College of Physicians and Surgeons of San Francisco, 1922; served during World War I; affiliated with San Pedro Community Hospital, where he died Aug. 5, aged 63, of carcinoma of the pancreas.

West, Harmon ⊕ Norwood, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1915; affiliated with Taylor Hospital in Ridley Park, where he died Aug. 17, aged 67, of meningitis and brain abscess.

Wilking, Spies Valentine ⊕ Butte, Mont.; Starling Medical College, Columbus, Ohio, 1898; member of the American Academy of General Practice; for many years secretary of the Silver Bow County Medical Society; died in St. Joseph's Hospital, Burbank, Calif., Aug. 10, aged 79, of intra-abdominal malignancy with metastases.

Wilkins, Howard Francis, Indio, Calif.; University of Southern California School of Medicine, Los Angeles, 1941; at one time on the faculty of his alma mater; owner of the Coachella Valley Hospital; died Aug. 6, aged 37, of acute coronary disease.

Willey, Perry Woodruff ⊕ Columbus, Ohio; Starling Medical College, Columbus, 1897; served on the staff of the White Cross Hospital; died Aug. 13, aged 80, of acute myocardial infarction.

KILLED IN ACTION

Engelbreit, Joseph James ⊕ University City, Mo.; St. Louis University School of Medicine, 1951; interned at St. Louis City Hospital; entered the Medical Corps, U. S. Air Force Reserve, in July, 1951, as first lieutenant; captain; flight surgeon on a bombing mission; killed in an airplane crash in Korea May 21, aged 25.

GOVERNMENT SERVICES

ARMY

Hospital News.—At the Brooke Army Hospital, Fort Sam Houston, Texas, on Sept. 16, medical officers and guests presented a symposium on cardiac arrest. The program, moderated by Col. Warner F. Bowers, chief of the surgical service, began with a statement of the problem by the chief of the cardiology section, Lieut. Col. Weldon J. Walker. Capt. Benton D. King, assistant chief of the anesthesia section, discussed the diagnosis and causative factors. The duties of the anesthesia and the surgical teams were discussed by Col. James G. Inman, chief of the anesthesia section, and Capt. Clinton A. Piper of the surgical service. A motion picture on cardiac resuscitation was presented by 1st Lieut. John G. Kralik. A demonstration of resuscitation equipment completed the program. Staff members of the medical center and interested civilian professional personnel were invited to attend the meeting.

PUBLIC HEALTH SERVICE

Appointments to Councils.—Mrs. Edward Curry, Topeka, Kan., and Mr. Louis E. Leverone, Chicago, have been appointed to serve on the National Advisory Heart Council, Surgeon General Scheele has announced. Mrs. Curry is president of the Kansas Council of Women and has served in various capacities with the American Association of University Women. Mr. Leverone, a leader in the development of business aviation, is the author of articles on vocational training, president of the Automatic Canteen Company of America, a past president of the Dartmouth College Alumni Council, a member of the Union League Foundation for Boys' Clubs, and a sponsor for the American Bible Society.

Members of the National Advisory Heart Council advise and make recommendations to the Surgeon General on programs of the National Heart Institute, established by congress through the National Heart Act in 1948. This is one of the seven National Institutes of Health at Bethesda, Md., main research arm of the Public Health Service. The council has 15 members composed of leaders in medicine, science, education, and public affairs. In addition to the appointed members of the National Advisory Heart Council, there are three ex officio members representing the Public Health Service, Veterans Administration, and Department of Defense. The council meets three times a year at the National Institutes of Health, Bethesda, Md., with its next meeting scheduled for Nov. 19-21, 1953.

Dr. Sidney Farber, scientific director of the Children's Cancer Research Foundation in Boston and professor of pathology at Harvard University Medical School, has been appointed to serve on the National Advisory Cancer Council. Dr. Farber is best known for his research on the chemotherapy of cancer, particularly leukemia, in children. With his associates at the Children's Medical Center, he conducts a diagnostic service for the benefit of general practitioners throughout the country who may obtain advice on individual cases. This service is made possible by funds from the Children's Cancer Research Foundation, founded by the Variety Club of New England in 1948 and later given financial support by the Boston Braves baseball team, the motion picture industry, and the Jimmy Fund. The chemotherapy clinic is housed in a new children's cancer research building constructed with these funds and equipped with the aid of a grant from the National Cancer Institute.

Lecture by Dr. Cori.—Dr. Carl F. Cori, professor of biological chemistry, School of Medicine of Washington University, St. Louis, Mo., presented the sixth of the 1953 guest lectures at the National Institutes of Health, Washington, D. C., Sept. 24. His address was "Enzymatic Analysis of the Structure of Starch and Glycogen." An authority on enzyme chemistry and carbohydrate metabolism, Dr. Cori is the recipient of the Lasker award, the Sugar Research Foundation award, and, jointly with his wife, the Squibb award and the 1947 Nobel prize in medicine and physiology.

The National Institutes of Health annual lecture series was established to facilitate interchange of information and to give appropriate recognition for outstanding scientific accomplishment. Each of the seven research institutes sponsors a lecture, with the eighth sponsored by the office of the director. This series will be repeated yearly, and the lectures will be published and distributed to various scientific centers.

VETERANS ADMINISTRATION

Psychiatric Residency Training Program.—The Cleveland Veterans Administration Hospital is accepting applications for their psychiatry residency program. It is approved for a three year residency in psychiatry. All psychiatric teaching and practice are psychoanalytically oriented under the supervision and direction of the psychiatry department of the Western Reserve University School of Medicine.

Opportunity for personal analysis and psychoanalytic training are available for qualified residents. Arrangements can be made to accept residents for one, two, or three years. Salary ranges are from $2,640 to $3,300 per year. The training benefits of Public Law 550 (Korean G.I. bill) may be obtained in addition to the residency salary. Applications may be obtained from Leon Ross, M.D., Chief, Professional Services, V. A. Hospital, Cleveland 29, Ohio; or Douglas D. Bond, M.D., Chairman of the Dean's Subcommittee for Psychiatry, University Hospitals, Cleveland 6, Ohio.

MISCELLANEOUS

Graduate Science Fellowships Offered.—More than 700 students with special abilities in science will be selected for a year of graduate study during the academic year 1954-1955 in the National Science Foundation's third annual graduate fellowship program. The closing dates for receipt of applications are Dec. 15, 1953, for postdoctoral applicants and Jan. 4, 1954, for graduate students working toward advanced degrees in science. National Science Foundation fellowships are awarded to American citizens who will begin or continue their studies at the graduate level in the mathematical, physical, biological, medical, and engineering sciences during the 1954-1955 academic year. Selections will be made solely on the basis of ability. The majority of the fellowships will go to graduate students seeking master's or doctor's degrees in science, although a limited number of awards will be made to postdoctoral applicants. Graduating college seniors in the sciences who desire to enter graduate school are encouraged to apply for the awards. Postdoctoral applicants will not be required to take the examinations. Applicants will be rated by special fellowship boards established by the National Academy of Sciences. Final selection will be made by the National Science Foundation.

Stipends for graduate fellowships will vary. First year fellows, students entering graduate school for the first time or those who have had less than one year of graduate study, will receive annual stipends of $1,400. Fellows who need one final academic year of training for the doctor's degree will receive annual stipends of $1,800. Fellows between these groups will receive stipends at the rate of $1,600 annually. The stipends for postdoctoral fellows will be $3,400 per year. Dependency allowances will be made to all married fellows. Tuition and laboratory fees and limited travel allowances will also be provided. National Science Foundation graduate fellows may attend any accredited nonprofit institution of higher education in the United States or similar institutions abroad. Applications may be obtained from the Fellowship Office, National Research Council, Washington 25, D. C.

FOREIGN LETTERS

DENMARK

Operative Treatment of Bronchogenic Lung Cancer.—In the thoracic surgery department of the Øresund Hospital in Copenhagen important advances have been made since 1944 in the treatment of cancer of the lung, more and more cases of which are being treated in this municipal chest hospital. In 1945 approximately 35% of all such cases in men in Copenhagen were dealt with in this hospital, whereas in 1950 this figure had risen to approximately 65%. Operable cancers particularly are being treated more frequently in this hospital, where facilities are provided for ambulant examination as well as inpatient treatment. Two members of its staff, Dr. Jens L. Hansen and Dr. Tage Kjaer, have lately undertaken an analysis (*Ugeskrift for Laeger* for May 28, 1953) of 638 consecutive cases of primary bronchogenic cancer in which the patients were discharged from the hospital or died between Jan. 1, 1944, and June 30, 1952. In the period 1944-1946 only 8.1% of all the patients were discharged after a successful primary lung resection. In the period 1951-1952 this figure was quintupled (41.6%). At first only about three such cases yearly were seen, whereas now some 50 such cases are seen each year. In the period 1944-1946, approximately one-third of all the patients were operated on, but less than 25% of the operations were successful resections. Most of the operations were exploratory or resulted fatally. Two-thirds of the patients already had inoperable cancers, usually because of metastases. Towards the end of the period under review, fully 70% of the patients could be operated on. In the period 1944-1946, two of every three operations were exploratory thoracotomies, whereas only one of every five operations is at present.

Dr. Hansen and Dr. Kjaer are greatly impressed by the value of frozen section microscopy during the operation itself as a means of determining the extent of the disease and limiting a resection to the necessary minimum. This test has now been adopted as a matter of routine and has been found to be so reliable that it is difficult to understand how it could have been dispensed with in earlier years. It is valuable in distinguishing healthy and diseased areas of the lungs, and this cannot always be achieved by any macroscopic examination. As Dr. Hansen and Dr. Kjaer remark, "In reality it is our pathologists who now decide the extent to which operations are to be carried out for lung cancer, and this is so also to a certain extent with tuberculosis and other diseases of the lungs." It is particularly the elderly patient with emphysema and a weak heart who benefits from the means of reducing the extent of a lung operation to the minimum.

Montebello Sanatorium for Neuroses.—In 1950 the Montebello estate was purchased for one million kroner by a group representing Greater Copenhagen and the province of Frederiksberg. Another million kroner was spent on equipment and the provision of beds for 100 patients. In the following year Montebello was formally opened as a sanatorium for treatment of neuroses, and in 1953 the number of beds was raised from 100 to 128. In certain respects Montebello holds a unique position in Denmark. There are, to be sure, other Danish sanatoriums that undertake the treatment of neuroses as distinct from psychoses, but these sanatoriums are linked up with asylums for treatment of psychoses and thus come to acquire an asylum flavor. Montebello, on the other hand, has no such link with any asylum, a fact to which its medical superintendent, Dr. Torsten Østergaard, attaches much importance. His patients are carefully screened in some other hospital before they are put on the Montebello waiting list. Psychoses, however slight, are a contraindication for admission, but the distinction between a psychosis and a neurosis is at times difficult, and it is inevitable that psychotics are occasionally admitted to Montebello. Psychopaths and drug addicts are not admitted, and patients with long-standing neuroses that have not been benefited by hospital treatment are also not eligible for admission. The ideal patient for admission is the patient with neurosis of comparatively recent onset that is uncomplicated by mental deficiency or hysteria. Considering that the criteria for admission are so rigid, it is remarkable that Montebello's waiting list is so long, many patients having to wait for several months.

A member of the Montebello staff, Dr. Gunnar Belling, has recently issued a report on 549 patients admitted to Montebello since April 1, 1951, and has shown what can be achieved by the many measures now available for the treatment of neuroses in a hospital. These measures include narcoanalysis and shock treatment, which are given only on the consent of the patient informed of their nature. Promising results have lately been achieved with modern group psychotherapy. Older and more conventional measures such as baths, massage, and gymnastics are also used. The use of drugs is somewhat limited, and as a rule the patient is encouraged to dispense with all drugs towards the end of his stay in the sanatorium. Discussions between patient and physician are encouraged, and a prominent feature of treatment is the aid given by social workers.

Measles in Greenland.—Recent reports in the Danish medical press of an outbreak of measles in 1951 in Greenland show how remarkably different is the behavior of this disease in Denmark itself and in Greenland. The disease is endemic in Denmark, where important outbreaks occur at intervals of only a few years. During the last 30 years some 20,000 to 70,000 cases have been reported yearly, with a mortality rate of about 0.1% during the last 10 years. Deaths from measles in Denmark are always due to secondary infection such as pneumonia. In Denmark measles is very rare in the first six months of life and is almost unknown in the first four months, presumably because of passive immunization by the mother.

The 1951 outbreak of measles in Greenland occurred in two main waves during which only 5 of 4,262 persons exposed failed to contract the disease. Among the very young babies who had measles, three were only a fortnight old. They had evidently been infected by their mothers who had been unable to give them the protection of passive immunization. In most cases the incubation period conformed to the conventional 13 to 14 days, but there were several cases with a much shorter incubation period of from 7 to 9 days. There were 77 deaths among more than 4,000 patients (a mortality of 1.8%) and as many as 25 of these deaths occurred in the prodromal stage of the disease, before the appearance of a rash. Such a sequence of events is almost unknown in Denmark.

Prophylactic treatment with the serum of convalescents and with gamma globulin may well have been beneficial, for the complication rate was only 28.4% as compared with 45.7% for the patients not thus treated. The mortality was, however, higher among the former, presumably because prophylactic treatment was reserved for children under 2 years, pregnant women, tuberculous patients, and persons not in good health. One complication, which is rare in Denmark, was edema of the lungs due to cardiac insufficiency. More than half of the 25 Greenlanders with this complication died of it. As was to be expected, the measles led to the outbreak of tuberculosis in many cases, and in a community of 363 persons who had been medically examined before and after the epidemic, as many as 19 new cases of tuberculosis were discovered. In the same community 14 persons already known to suffer from tuberculosis died of it during or shortly after the epidemic.

The items in these letters are contributed by regular correspondents in the various foreign countries.

ITALY

Italian Section of International College of Surgeons.—The Italian section of the International College of Surgeons held its fourth convention in Rome. The inaugural ceremony took place in Campidoglio on June 11, with Professor Rebecchini, the mayor of Rome, welcoming the surgeons. Among the speakers were Professor Jackson from the United States, who represented the foreign delegates, and Dr. Max Thorek of Chicago, the permanent secretary of the International College of Surgeons.

The first topic was syndromes due to venous obstruction in the upper extremities. Professor Tagariello reported his phlebographic studies of the return circulation of the arm, which were undertaken in an attempt to interpret correctly phlebograms of the axillary and subclavian veins that sometimes have been erroneously interpreted. Some authors had considered such roentgenograms the basis for a diagnosis of obstructed venous circulation of the arm. His studies revealed that the axillary vein may sometimes appear on roentgenograms to be occluded in persons with normal return circulation. This is particularly likely to occur when the contrast medium is injected into the cephalic vein rather than the basilic vein or when the deep veins are visualized. Such images are due to a backward flow of the opaque medium and do not indicate the presence of an obstruction.

His studies also disclosed how some roentgenographic images of the subclavian vein result from interruption or stenosis of the column of opaque medium. Such images depend on the more or less closed position of the terminal valve of the vein. The function of this valve is to prevent the reflux from the innominate vein, which causes an arrest or a decrease of the diameter of the column of contrast medium. A radiological contrast is therefore formed between the opaque column and the blood that has not become opaque. This, flowing back into the valvular sinuses, causes their distention, which draws the lobes more or less close. These roentgenographic pictures, which some American authors have considered to indicate intermittent obstruction of the subclavian vein, have no diagnostic value, the speaker said, unless they are considered along with the relative collateral circulation.

On the basis of his observations on 15 patients with the syndrome caused by an obstructed return circulation of the upper extremity, Professor Tagariello reviewed the subject known in the literature as effort thrombosis of the axillary and subclavian veins. He established the exact physical manifestations of the syndrome, distinguished a continuous type and an intermittent type, and emphasized that some authors have considered as intermittent some syndromes in which there is a true continuous and persistent obstruction. These authors interpreted as a sign of interrupted obstruction the cessation of the symptoms that, although typical of the continuous obstruction syndrome, is instead the expression of the relative insufficiency of the collateral circulation. This insufficiency becomes manifest only when muscular activity of the arm requires a venous flow greater than the substitute pathways can offer.

Professor Tagariello distinguished initial symptoms that are common to the two types of thrombosis. They generally appear when the person is performing manual labor or physical exercise, and consist of pain in the shoulder or the clavicular region, venous turgidity, cyanosis, swelling of the tissues, and increased venous pressure. In the syndrome of continuous thrombosis these symptoms become aggravated gradually, even if the arm is at rest, and there are in addition edema and subcutaneous venous reticulum in the arm, the shoulder, and the homolateral area of the chest. After an interval that may extend up to several months, all the symptoms regress or disappear except the venous reticulum, which becomes more visible. However, pain, venous turgidity, and cyanosis reappear if any work is performed with the arm that requires increased circulation. This is the so-called false interruption. In the intermittent type of syndrome the initial symptoms disappear completely when the movements or the positions of the arm that have caused them are discontinued, but the symptoms reappear every time the same position or the same movements are resumed.

Treatment varies and depends on whether it is possible to establish the exact location, extension, and nature of the obstruction. Anticoagulant therapy does not give good results in intrinsic obstructions. Resection of the thrombosed vein does not cure the form that recurs with effort. Phlebotomy with removal of the clot is rarely performed, although it is a radical and efficacious treatment. The obstruction should be removed, if possible, when it is extrinsic. The lower part of the minimus scalenus and the entire subclavian muscle should be excised when the subclavian vein is compressed between the scalenus and the clavicle or between the subclavian muscle and the first rib. During the discussion that followed, many physicians present reported their personal experiences with syndromes due to obstructed venous flow of the arm.

Dr. Sered, from Chicago, discussed treatment of tuberculosis of the cervix uteri, which, he emphasized, is commoner than it appears to be from the literature. He found it in 9 of 55 patients who had genital tuberculosis. The infection may arise because of direct contact or it may appear as a secondary infection from far removed foci. The commonest initial diagnosis is carcinoma of the cervix, whereas the most frequent clinical manifestation is vaginal discharge of blood.

Dr. Bornemeier, Chicago, discussed the evaluation of surgical risk in aged persons. A delayed intervention or a decision for nonintervention, owing to inability to evaluate the risk, increases the mortality for a condition that a timely intervention would cure. All the criteria that are followed for a middle-aged adult should be used for aged patients, although they must be applied more vigorously because aged persons react differently to trauma. To show that a careful evaluation assures a satisfactory percentage of good results, the speaker cited a series of 50 operations that a group of surgeons performed in aged persons in one year.

The following day a symposium on angiocardiosurgery was held under the chairmanship of Professor Darget, Bordeaux. Dr. Gorelick, New York, discussed the use of cardiopericardiopexy in coronary and rheumatic heart disease. According to Dr. Gorelick, this operation revascularizes the myocardium in such conditions. In this way the ischemic myocardium is made hyperemic and its function is improved and strengthened so that eventually an operation can be performed on the valves.

Dr. Di Matteo, from the surgical clinic of Rome, reported on the electrocardiograms that he and his colleagues, Drs. Conti and Danese, obtained before and after surgical interventions for chronic pericarditis.

Prof. C. P. Bailey, Philadelphia, discussed surgical treatment of aortic stenoses. It is advisable, he said, to intervene by the ventricular approach when the aortic stenosis is associated with mitral stenosis; he had a mortality of 6% in 16 patients with such condition that he operated on. When the lesion is limited to the aortic valve alone, it is wise to intervene using the old method, namely, through the aortic arch. In fact, by using the aortic approach, it is possible to see the aortic valve and the double-edged dilator that he made can be used. Professor Bailey substantiated his report with many diagrams and pictures.

Prof. Achille Dogliotti, director of the surgical clinic of Turin, reported his results with commissurotomy of the mitral valve. He obtained good results in 50 instances in which he used a valvulotome that he made. It consists of a metallic ring that has a small blade on the external surface. He stressed the necessity of operating on a bloodless heart in these patients by use of extracorporeal circulation. He succeeded in doing this recently in one patient.

Professor Valdoni, a pathologist and surgeon from the University of Rome, reported on the late results of more than 100 interventions in patients with mitral stenosis. He pointed out the contraindications for this intervention and said that he is in favor of digital valvotomy. He then asked Professor Bailey to talk about his experience in surgery of mitral stenosis. Professor Bailey discussed the results of his experience (846 interventions for commissurotomy) and confirmed his advocation of instrumental dilatation and the opportunity of extending its indications. To close the convention Professor Paolucci performed a series of major operations before those attending.

LONDON

The Hour of Birth.—One of the largest and most carefully controlled statistical investigations yet recorded of the age-old problem of the hour of birth has just been published by Enid Charles (*Brit. J. Prev. & Social Med.* 7:31, 1953). It is based upon a series of over 16,000 live and stillbirths in Birmingham in 1951-1952. For the greater part of the investigation the analysis was restricted to pregnancies and labors free from any pathological disturbance up to the time of delivery.

The percentage distribution by times of onset of labor showed a clearly marked peak at 2 a. m. (7.4%) to 3 a. m. (6.1%). In the six hour period from 11 p. m. to 5 a. m., 37% of labors began, compared with the expected 25%. The greatest difference between night and day is shown by comparing the 12-hour period from 9 p. m. to 9 a. m., when 62% of the labors began, with the 12 hours from 9 a. m. to 9 p. m., when 38% began. The point of minimum onset is less clearly marked, but occurs between 1 p. m. and 2 p. m. (2.4%). These differences were more marked in primigravidas than in multiparas. Thus, taking the two six-hour periods, from 11 p. m. to 5 a. m. and from 11 a. m. to 5 p. m., the percentages with onset of labor at these times were 48.1% and 13.2% for primigravidas, and 36.4% and 17.4% for multiparas. These figures are for domiciliary births. Those for institutional births showed less difference, the corresponding figures for primigravidas being 38.6% and 16.7% and for multiparas 34.6% and 17.7%.

The seasonal variation was not marked, though there was a tendency for a sharper peak in the summer than in the winter months. Miss Charles suggests that the summer-winter difference may be a response to red light, with the onset of labor occurring somewhat earlier. This suggestion can only be speculative, however, in the absence of clear-cut seasonal differences, particularly if the artificial conditions of life in a large smoke-polluted city are considered.

The 3,794 cases that were excluded from the above analysis because of "some features likely to affect the course of labor more or less adversely" (e. g., toxemia of pregnancy or presentation other than vertex), and of the 386 cases of stillbirth were compared. There seemed to be a tendency for the onset of labor to occur earlier in the day with what may possibly be increasing severity of pathology. That is, 30.5% of labors that resulted in stillbirth began in the first period compared to 22.9% of the normal births.

The curve of delivery times was much flatter than that of times of onset. The 12-hour period with the most deliveries was between 9 p. m. and 9 a. m., with 55.6% of all deliveries: 30% occurred in the six-hour period from 2 a. m. to 8 a. m. instead of the expected 25%. Parity made a considerable difference. Thus, for primigravidas the 12-hour period with most deliveries was 3 a. m. to 3 p. m., with 53.2% of all deliveries; 28% occurred between 6 a. m. and noon. Practically speaking, first deliveries are evenly distributed throughout the 24 hours. For multiparas the 12-hour period with the most deliveries was 9 p. m. to 9 a. m., with 57.5% of all deliveries; 31.4% occurred between 2 a. m. and 8 a. m. An analysis of the modal durations of labor suggested that in labors starting at 11 p. m., midnight, and 1 a. m. the mode is reached early, whereas in labors starting at 4 a. m. to 7 p. m. it is reached late. The author suggests that when labor starts during sleep the first few contractions may not wake the patient so that the duration appears shorter. She notes that this would hardly seem to account for the shorter duration of labors that begin at 10 and 11 p. m., and speculates that the uterus may be more relaxed at the end of the day, with a slight advantage gained in the course of labor.

An Elizabethan Banquet.—St. Thomas Hospital in London is one of the few hospitals in England that can span the 400 years intervening between the reigns of the two Queen Elizabeths. It is also one of the five Royal Hospitals of the City of London. Although its origin is lost in the mist of history, it can trace its ancestry back to at least the 12th century. Like so many religious institutions, it was a victim of the avarice of Henry VIII. In 1551, King Edward VI granted Letters Patent refounding the Hospital. The foundation charter, however, is dated June 26, 1553, 10 days before the King's death. This coincidence of the 400th anniversary of the refounding of the hospital and the coronation of Queen Elizabeth II has just been celebrated by an Elizabethan banquet.

The setting for the banquet was a marquee on the hospital's Sports Grounds at Stoke D'Abernon in Surrey. This is one of the loveliest corners of Surrey, with beautifully turfed playing fields set amid woodlands, with the old village church, famous for its brasses and a history dating back to the Normans, in the background. The menu provided ample justification for the title of the occasion and included swan, peacock, badger pie, and salmon.

The toast of the evening, "St. Thomas's Hospital and Medical School," was proposed by Mr. H. L. O. Flecker, the Headmaster of Christ's Hospital, the famous Blue-Coat School, which is another of the Royal Hospitals of London. He epitomized the characteristic feature of St. Thomas's Medical School by pointing out that great men are great men no matter where they are educated. The criterion of a medical school is the general standard of its graduates, and he had no hesitation in saying that, so far as St. Thomas's was concerned, the record stood high as judged by the standards of the men it had sent into general practice, there to maintain quietly and constantly a standard of service, integrity, and sympathetic understanding that had done much to maintain and enhance the prestige of general practice in Great Britain.

Poliomyelitis.—Some anxiety is being felt in official circles about poliomyelitis this summer. Actual figures so far are not alarming; there were 73 cases during the week ended June 13 (an increase of 22 over the previous week) and 65 during the week ended June 20. Although these figures show no great rise compared with 1952, the curve of reported cases during the last three months has been parallel to, and even sometimes slightly above, that of the highest figures for the period 1944-1952. It is this fact, in conjunction with memories of what happened in Copenhagen last year, that is disturbing the authorities, and preparations are being made for a serious outbreak. Several centers in this country are already equipped and staffed to deal with poliomyelitis. These, however, are few, and in too many instances apparatus and trained personnel are not found in the same institution.

Skin Sensitization to Antibiotics in Medical Personnel.—Early in the year, reports were received by the Ministry of Health that nurses who gave many injections of streptomycin were becoming sensitized to the antibiotic and that the numbers affected were causing anxiety in some areas. A survey was therefore carried out in 70 local health authorities and 76 chest hospitals and sanatoriums to determine whether sensitization to antibiotics had occurred among the nursing staffs. The total number of cases reported was 256.

The population exposed was ascertainable in only eight local authorities and four hospitals. In these the incidence was 4.3% for the former, 1.8% for the latter, and 3.5% for the two groups combined. The sensitizing agent was not ascertainable in all cases, but in 86 local authority cases and 102 hospital cases the patient was sensitized to streptomycin. In 73 local authority cases and 7 hospital cases there was sensitization to penicillin. There was one case each of sensitization to chloramphenicol and *p*-aminosalicylic acid. In many cases there was sensitization to more than one antibiotic and in a few sensitization to other drugs as well. In most cases the hands, face, eyes, and neck were involved. Medical staff, hospital nursing staff, district nurses, and hospital pharmacists were all involved.

On the recommendation of his Standing Medical Advisory Committee and the Central Health Services Council, the Minister of Health has circulated to all hospitals and local health authorities the following note prepared by a small committee of experts.

"It is realized that the technique here recommended following expert advice and ad hoc experiments, whilst in conformity with the practice of many doctors, differs markedly from that usually taught to nurses. . . . Contamination by the solution of the skin of both hands and face can readily occur when the syringe is held vertically at eye level and air expelled from it before injection: bubbles bursting at the tip of the needle then liberate a fine spray of the solution. In order to prevent sensitization, this operation must not be conducted in this way. The air should be expelled from the syringe with the needle still in the bottle from which the solution has been withdrawn. Care should be taken to support the piston during and after withdrawal, so that further air does not enter. Special care must be taken to ensure that the needle is firmly attached to the syringe so that no sudden leakage occurs under pressure.

"Contamination of the hands with solution can still take place if the needle used for withdrawal is removed and another substituted for the injection into the patient. This is commonly done, either because a wide-bore needle facilitates withdrawal of viscous fluids, or because it is believed that perforation of the rubber cap blunts the needle. This belief is unfounded; it has been shown by experiment that piercing these rubber caps as many as 100 times does not affect the sharpness of the needle. The second precaution advised is therefore that the same needle be used for both withdrawal and injection. This is particularly necessary when giving streptomycin, and since this solution is not viscous, as fine a needle (e. g., no. 14 or even no. 17) may be used as is desired. After use the syringe should be rinsed out in plenty of water, and the doctor or nurse should then immediately wash the hands to rid them of any traces of solution left on them."

PARIS

Improvement of Smallpox Vaccine.—For about 20 years a recrudescence of complications, especially postvaccinal encephalitis, following Jennerian vaccination, has been reported. During these last years, Prof. G. Ramon, R. Richou, and associates have endeavored to solve this problem by the preparation of a vaccine with diminished, or totally suppressed, virulence, while preserving its immunizing properties. They prepared an anavaccine by adding a very small dose of Formol (formaldehyde in wood alcohol and water), 0.02 to 0.05 cc. of the commercial Formol solution per 100 cc. of vaccine, and heating to 15 to 20 C for a variable period. Such a vaccine provokes in the horse the elaboration of antibodies that protected rabbits against inoculation of the same virus. This principle was conversely confirmed by similar experiments, also performed on the horse, with the aphthous virus and anavirus. Nélis and Lafontaine also noted that the addition of a very small dose of Formol reduces or totally suppresses the encephalitogenic potency of strains of virus having such a property.

The encouraging results obtained with this vaccine induced Ramon and associates to use the culture of smallpox viruses in the artificial culture mediums recommended for the culture of the aphthous virus. Among the advantages of such a virus are the possibility of abundant and economical production, a bacteriologically pure virus, and the ease with which it is attenuated or transformed into an anavirus. Moreover, such an antismallpox vaccine may be used by percutaneous, intradermal, or subcutaneous administration. It may also be used along with other vaccines, for example, associated with anavirulent vaccines (whooping cough anavaccine or influenza anavirus), or with anatoxins (diphtheria and tetanus). Investigations for the improvement of antismallpox vaccines and the prophylaxis of postvaccinal complications are now in progress, as reported to the Academy of Sciences by these authors.

Mediastinography.—A new technique for the exploration of the mediastinum has been evolved by Condorelli (Italy) that consists in infiltrating air between the different organs of the mediastinum so as to separate them. In France recently Professor Bariety has reported on his own technique. He uses a long needle with a sharp, pointed chuck, which enters the trachea 2 cm. above the manubrium of the sternum and then is pushed in perpendicularly so as to penetrate the tracheal wall. The pointed chuck is then replaced by one with a blunt pointed end provided with a small spring. The needle is then inclined at 30 degrees downward, and contact is sought with the posterior fibrous wall of the trachea, which is perforated guardedly. Penetration into the intertracheoesophageal space is indicated by a special sensation and slight recoil of the chuck spring followed by a release. The chuck is then withdrawn and the needle connected to an insufflation apparatus of the Küss type. For 20 minutes 300 to 600 cc. of air is injected under pressure of 20 to 30 cc. of water. According to the author, this technique is quite safe but is contraindicated in pulmonary tuberculosis with positive sputum and other infections of the respiratory tract.

SWEDEN

A Census of Cardiovascular Diseases.—The census recently started in Malmö to ascertain the incidence of valvular disease of the heart is one of many aspects of the growing interest in the cardiovascular diseases. Investigations published in 1950 by Dr. Gunnar Biörck and Dr. Blomqvist have shown that the cardiovascular diseases are responsible for about 40% of all the deaths in Sweden. While the mortality from all diseases combined has fallen 25% in the period 1911-1944, the part played in the same period by the cardiovascular diseases has increased by 76%. If the average duration of these diseases is 10 years, then some 250,000, or 3.5%, of the population of Sweden suffer from them at the present time. This figure may be an underestimation if one judges by the United States where the figure is double, 7%. Among the 250,000 with cardiovascular disease are some 100,000 persons under 67 years of age.

Dr. Biörck, who is attached to the Malmö General Hospital, has drawn attention to the curious fact that, while Sweden is endowed with numerous national associations for combating special groups of diseases and while the United States has the American Heart Association, no such organization has hitherto been established in Sweden. Perhaps a general appeal for the public to take part in a campaign against the cardiovascular diseases would be untimely since at present no adequate response could be made to a demand for more hospital accommodation. Effective education of the public with regard to the cardiovascular diseases presupposes knowledge of their etiology and mastery of adequate treatment. On these two points, we still have far to go, and, if the public were to appeal for examination and treatment on a much greater scale than heretofore, the necessary personnel and laboratory equipment would not be available. Dr. Biörck is not discouraged by these reflections, and in his planning for the future he refers to the achievements already realized at the cardiac clinic of the South Hospital (Södersjukhuset) in Stockholm under the direction of Professor Nylin and his staff.

Long-Acting Corticotropin (ACTH) for Asthma in Children.—At the children's department of the Caroline Hospital (Karolinska Sjukhuset) under the direction of Professor A. Wallgren, two forms of corticotropin (ACTH) have been tested for their effects on the asthma of childhood. Reporting on these tests in *Nordisk medicin* for June 5, 1953, Drs. C. G. Bergstrand, Inga Engström, and S. Kraepelien point out that, in one series of tests, ordinary corticotropin was given to 13 children and long-acting corticotropin to 11 children most of whom suffered from severe status asthmaticus and were refractory to ordinary antiallergic treatment. While the ordinary corticotropin was given by injection four times a day, the long-acting corticotropin was given only once every second or third day and, in some cases, only every fifth to seventh day. With ordinary corticotropin the asthma responded usually on the second day of treatment, and the results were remarkably good; however, the duration of freedom from attacks varied from less than a day to 15 weeks. With long-acting corticotropin there were also wide variations in the duration of remissions; the longest lasted three months. Ordinary corticotropin proved to be the more satisfactory alternative in desperate cases requiring rapid results. But long-acting corticotropin is to be preferred as it allows for outpatient treatment with an interval of days between each injection. This means that asthmatic patients can be treated with long-acting corticotropin over a considerable period without too great risk of side-effects.

Thyroid Gland in Relation to Neuromuscular Disease.—Millikan and Haines discuss disorders in which dysfunction of the thyroid and of the muscles are associated on the basis of the following classification: (1) thyrotoxicosis and (*a*) myasthenia gravis, (*b*) chronic thyrotoxic myopathy, (*c*) periodic paralysis, (*d*) exophthalmic ophthalmoplegia; (2) hypothyroidism and altered muscular function. Clinical experience and pharmacological evidence indicate that myasthenia gravis and hyperthyroidism are separate diseases. The administration of neostigmine does not change the weakness of hyperthyroidism but does greatly alter the weakness of myasthenia gravis. Patients with hyperthyroidism show a normal response to the injection of d-tubocurarine, whereas patients with myasthenia gravis are highly sensitive to this drug. There is no consistent relationship between the two diseases. When they occur together, treatment is a serious problem. The use of I^{131} may be of great aid in hyperthyroidism, since thyroidectomy often cannot be performed safely. Chronic thyrotoxic myopathy is fairly common. The weakness associated with this disorder is most frequently in the pelvic girdle, although the shoulder girdle and peripheral muscles may be involved. The stretch reflexes are normal. The weak muscles are not strengthened by the administration of neostigmine and are not unusually sensitive to curare. The coincident occurrence of periodic paralysis and hyperthyroidism is more frequent than would be expected to occur by chance. There has been improvement or complete relief of the periodic paralysis after effective treatment of the hyperthyroidism. Clinical and laboratory evidence indicates that the two are separate diseases. Periodic paralysis may exist in some instances as a latent abnormality that becomes manifest as hyperthyroidism develops. The pathogenesis of exophthalmic ophthalmoplegia has not been explained. The ophthalmoplegia is not produced by a mechanism similar to that which produces ophthalmoplegia in myasthenia gravis. The exophthalmos is most likely a result of enlargement of the contents of the orbit, in which edema, infiltration with lymphocytes, and a marked increase of the fat in the extraocular muscles and other orbital tissues play a part. The ophthalmoplegia is apparently a result of the intrinsic changes in the extraocular muscles. Hypothyroidism produces abnormality in the contractile mechanism of muscle. This is not observed in other diseases which lower the basal metabolic rate and is not the same as myotonia. Thyroid dysfunction has been shown to be intimately associated with muscle function. In the cases studied this effect appears to be primarily upon intrinsic muscle metabolism rather than on the nervous system with secondary effects upon muscle action.

Prognosis in Diabetic Acidosis.—Zieve and Hill evaluate measurements thought to be of prognostic importance in diabetic acidosis by comparing their effectiveness in differentiating between a sample of patients who lived and a sample of those who died. Measurements analyzed were (1) age, (2) associated condition, (3) degree of unconsciousness, (4) duration of coma, (5) mean blood pressure, (6) blood urea nitrogen, (7) blood sugar, and (8) carbon-dioxide-combining power. The order of importance of the significant prognostic variables was age, blood pressure, associated condition, blood urea nitrogen, degree of unconsciousness, and duration of coma. Blood sugar and carbon-dioxide-combining power did not significantly differentiate between the two groups. When considered simultaneously, with allowances for their interdependence, the measurements may be regrouped into three levels of significance, as follows: highest, associated condition, blood sugar, and blood urea nitrogen; intermediate, blood pressure and duration of coma, and lowest, degree of unconsciousness. Age had no independent contribution, and carbon-dioxide-combining power remained insignificant. For a given degree of severity, a high blood sugar level was a favorable prognostic sign. The severity score, representing an optimal linear combination of the independently significant variables, was three times as effective as the prognostic factors considered individually. A simplified tabulation is presented enabling ready application of the formula in practice.

Shock-like State Due to Transfusion of Blood Contaminated with Gram-Negative Bacilli.—Braude and associates present the case of a man, aged 28, in whom a severe transfusion reaction developed due to massive bacterial contamination of banked blood. The three chief clinical characteristics of the transfusion reaction were fever, hypotension, and pain. Uremia, secondary to anuria, was the most prominent complication. Two species of bacteria were isolated from the bottle of transfused blood. One of these gave the typical reactions of E. freundii. The second organism belonged to the coliform group and resembled Aerobacter aerogenes. It was classified as a coliform bacillus of intermediate type. A total of 3 × 10^9 bacilli were counted in 1 ml. of the contaminated blood, using poured plates made with appropriate serial dilutions. The patient was promptly treated with polymyxin B, chlortetracycline (aureomycin), chloramphenicol, and penicillin. Subsequent studies bore out the logic of using several antibiotics. Polymyxin B proved to be highly bactericidal against the E. freundii and the coliform bacillus isolated from the patient but not against the coliform bacillus in the bottle. Chlortetracycline proved bactericidal for both coliform bacilli, but not for the E. freundii. Within 16 hours after treatment with antibiotics was started, the patient's blood had been sterilized. The hypotension was treated by arterenol. The amount required was far greater than that ordinarily recommended for treating shock. The patient received 80 mg. on the second day and 96 mg. on the third day. The doses required testify to the profound and persistent nature of the hypotension. When enough arterenol was being injected, the blood pressure was promptly restored and the restlessness, apprehension, confusion, and hyperventilation of the hypotensive state disappeared. Urinary output was restored. Gradual reduction in concentration of arterenol permitted eventual weaning of the patient from arterenol. The source of the contamination was investigated and found to be related to the accidental use of contaminated syringes for withdrawing blood from the bottles to obtain specimens for the Kahn test. Many of these syringes

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for *periodicals should be addressed* "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. *Periodicals published by the* American Medical Association are not available for lending but *can be supplied* on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

had been used to enter bottles of blood without reactions having occurred. Undoubtedly many bloods were contaminated in this way, but the bactericidal or bacterial-suppressive action of many bloods, as well as the slow rate of bacterial growth in blood in the refrigerator, protected most recipients. Undoubtedly, the coliform bacillus isolated from the patient was the same as, or a closely derived variant of, the coliform bacillus present in the contaminated bottle. The differences between the two strains suggest that variation had been brought about by passage through a host. Slight hope was held that the induced bacteremia might be beneficial to the patient. This hope was based on the known necrotizing effect of Serratia marcescens on tumors. No beneficial effect materialized. The patient later died of Hodgkin's disease.

Congenital Night Blindness.—The type of night blindness with which this report is concerned is present at birth, is stationary, occurs in about equal numbers of males and females, and is not associated with ophthalmoscopic abnormalities, In France the disorder is known as the "Nougaret type of night blindness," it having been traced through 10 generations of the Nougaret family. This pedigree reveals that an unaffected child of parents with this type of night blindness never carries the disease, and none of the descendants of such a child are involved. The history of an American family with this type of congenital stationary night blindness is presented. The case of a physician's wife, aged 53, is presented in detail. When she came for a refraction study, she mentioned incidentally that she had had night blindness since birth and stated, on being questioned, that numerous other members of her family (including her father, then dead) were similarly affected. With a correction of +0.75 sph., visual acuity was 20/20 in each eye. Ophthalmoscopic examination revealed nothing abnormal. The visual fields, as examined with an illumination of approximately 7 foot-candles, were normal. Subsequently the authors examined two of this woman's sisters, two of her nieces, a nephew, and a grandnephew. Of these seven members all had normal fundi, four had night blindness, and three had normal dark adaptation. Dark adaptation tests, absence of the Purkinje phenomenon, electroretinography, and clinical studies indicated a complete lack of rod function. An unusual opportunity was thus presented for the study of the visual capacity of persons who have normal (or almost normal) cone function only. One subject had completely normal cone function, and the other three had cone thresholds 0.20 and 0.40 log units above the highest normal; this is not a large deviation from normal. Color vision tests on one patient indicated mildly defective blue-yellow vision and low-normal red-green vision. Refraction showed small to moderate amounts of hyperopia or compound hyperopic astigmatism; the visual acuity with correction was normal. The visual fields were normal until the illumination was greatly reduced. A contraction of 20 to 40 degrees in the peripheral fields was present when the illumination was between 0.01 and 0.001 f.-c.; below the latter level the patient apparently saw nothing. Recently, electroretinograms have been recorded on two of these night-blind patients. The electrical responses obtained tend to confirm the lack of rod-receptor mechanism.

Cardiac Arrest and Ventricular Fibrillation: Experimental Study.—The effect of acute hypoxia and hypercapnia induced by breathing mixtures containing varying amounts of oxygen and carbon dioxide on the cardiac arrest produced by vagal stimulation was studied in normal and in chronically hypoxic dogs. Three methods for producing chronic hypoxia in dogs are described. In the normal dog, hypercapnia significantly enhances vagal cardiac arrest. In the chronically hypoxic dog, hypercapnia does not enhance vagal arrest. The effect of acute hypoxia and hypercapnia induced by breathing mixtures containing varying amounts of oxygen and carbon dioxide on the cardiac arrhythmias induced by cyclopropane anesthesia with intravenous administration of epinephrine was also studied. Acute hypoxia appears to make cyclopropane-epinephrine arrhythmias more prolonged, whereas hypercapnia does not appear to have any specific influence. In one-third of the dogs with chronic hypoxia, ventricular fibrillation was induced by vagal stimulation, whereas this arrhythmia did not occur with vagal stimulation in previously normal (nonhypoxic) dogs.

Cardiac Arrest in Infants and Children.—This study covers a 23-year period and records 66 cases of sudden arrest of the heart in children occurring in the operating rooms of two hospitals. There were eight cases (group 1) during the first five years of this study. These were collected from the records at the Massachusetts General Hospital in 1930. There were 58 cases during the last 18 years, occurring at the Los Angeles Childrens Hospital; 23 of these cases (group 2) of cardiac arrest were encountered in the general surgical services and 35 in patients with cardiac conditions (group 3). The 23 cases of cardiac arrest in the general surgical services occurred among a total of 57,600 consecutive general operations at the Los Angeles Childrens Hospital during the 20 year period 1932 to 1952. This is an incidence of 1 case of cardiac arrest in 2,504 operations. During the last 5 years there has been an alarming increase in incidence to 1 in 1,128 operations. In cardiac operations the incidence of cardiac arrest was 156 times more frequent; 35 cases of arrest occurred in 550 cardiac operations. The alarming increase in the incidence of cardiac arrest during the last five years in the general surgical service is not explained; it appears to be a problem of anesthesia, dependent perhaps on the dead space and the respiratory resistance in the mask and tubes leading from the face. The plan of management now in operation at the Los Angeles Childrens Hospital consists of immediate recognition of cessation of the heart beat during surgery by strapping a stethoscope to the precordium before operation. When arrest is apparent, the heart is exposed through the fourth interspace and massage is started. Oxygen is artificially supplied to the lungs. Whereas prior to the adoption of the present plan of management no child lived after cardiac arrest, now 25% completely recover.

Diospyrobezoar.—The term diospyrobezoar was suggested by DeBakey and Ochsner for concretions of persimmon origin in the gastrointestinal tract. In the 14 cases of diospyrobezoars reported by O'Leary there was a history of ingestion of persimmons. Diospyrobezoar was discovered at surgery or necropsy. The histories of 8 of the 14 cases are presented, 6 others having been described elsewhere. Data on 46 cases of diospyrobezoar reported in the literature are also presented. The persimmon is a plum-like fruit of a tree which belongs to the genus Diospyros. The orange-colored fruit contains multiple seeds. Gastric acidity seems to play a part in the development of diospyrobezoar, one report indicating that free acid was found in all but 2 of 26 cases with this type of bezoar. A soluble phlobatannin is present in the persimmon, and, particularly with an empty stomach, the ingestion of unripened or unpeeled ripened persimmons would allow coagulation and contact of the phlobatannin. A bezoar would occur by aggregation of fragments. The diospyrobezoar is found predominantly in males. Acute abdominal symptoms such as pain, tenderness, nausea, and vomiting may develop within 24 hours after ingestion, but these disappear in a few days and later milder abdominal symptoms appear. Many patients do not seek medical aid for these until they become severer in the late course of the disease, due to gastric ulcer or to intestinal obstruction. Ten of the 14 patients had a gastric ulcer. On hospitalization severe bleeding existed in five, penetration in four and a free perforation in one of the 10 with gastric ulcer. Acute intestinal obstruction occurred in one case. The preoperative diagnosis of a diospyrobezoar depends on fluoroscopy to establish the free mobility of an intragastric mass. Multiple diospyrobezoars may occur. A diospyrobezoar warrants careful exploration of the entire gastrointestinal tract. Surgical removal is advisable, and careful intragastric exploration is necessary to determine the presence of an ulcer. Three of the 14 cases observed at the author's hospital terminated in death, and necropsy revealed perforation of a gastric ulcer as the cause. The perforation had occurred in the preoperative period in one patient and during the postoperative period in two.

Failure of Antibiotics in Infectious Mononucleosis.—Walker points out that the extremely varied course of infectious mononucleosis has led observers to attribute beneficial effects to many therapeutic agents, all of which have eventually proved ineffective. Recently antibiotic agents such as chlortetracycline (aureomycin) and chloramphenicol have been found effective in altering the course of infectious mononucleosis by some investigators, whereas others concluded that these drugs were ineffective. Walker describes studies on 78 patients with infectious mononucleosis, which he divides into several groups, depending on the treatment used. He feels that the closely comparable total course of the disease process in each of the treated or untreated groups is clear evidence of the failure of chlortetracycline and chloramphenicol to alter the course of the disease.

Occipitalization of the Atlas.—McRae and Barnum observed enough anomalies in the region of the foramen magnum to allow their separation into groups. This report deals with one specific type of congenital bony deformity at the foramen magnum. The lesion has been called occipitalization of the atlas or assimilation of the atlas to the occipital bone. They report 25 cases. The morphology, embryology, and the clinical aspects of these cases are discussed. The major symptoms of cervical cord compression due to the soft tissue and bony abnormalities associated with occipitalization of the atlas are weakness and ataxia of the lower extremities. Numbness and pain in the upper extremities is a prominent complaint, although the upper extremities are often involved also on the motor side. Sensory complaints in the lower extremities seem to be rare. Occipital headache may be present, as may blurring of vision and diplopia. Bladder symptoms are rare. Head or neck trauma would seem to play some part in the onset of symptoms in a condition which has presumably been present since birth. The objective findings comprise chiefly hyperreflexia, Babinski and Hoffmann reflexes, weakness, and other long tract signs in both the upper and lower extremities. Ataxia may be present to a marked degree, and nystagmus is frequent. Sensory findings are less frequent, but posterior column signs may be seen in the lower extremities—rarely in the upper. Hypesthesia is also seen in the extremities. This syndrome recalls a similarity to multiple sclerosis, especially with the fluctuation in the intensity of the signs and symptoms in some cases. The fact that over one-third of these cases were previously misdiagnosed, and most frequently as multiple sclerosis, would lend emphasis to the possible confusion of the entities. Therefore, the knowledge of and search for such cervical anomalies in cases of the syndrome described is of the utmost importance, especially in view of the possibility of benefit by surgical correction of the condition.

Outcome in Survey-Detected Tuberculosis.—Results of the observation of 656 persons who were diagnosed as having pulmonary tuberculosis as a result of chest roentgenographic surveys and who were followed for an average of 2.7 years are presented. Active disease was found more frequently in younger than among older persons. During the course of this observation, 23 died from tuberculosis and 10 others died from nontuberculous causes. There were 114 instances of progression of tuberculosis. Once the persons observed were classified according to clinical status, the frequency of progression was fairly uniform regardless of age, at least among white persons with minimal disease. Progressions and deaths occurred in fairly predictable fashion. The relative frequency of each event was closely related to the initial clinical classification. Careful clinical evaluation of each person found to have suspected tuberculosis on a miniature film is of great importance in predicting the likelihood of future disability or death. Mortality from tuberculosis was approximately three times as high among the nonwhites as among the whites. Deaths among those in the group with active disease appeared to be approximately two and one-half times as frequent as among other persons. Nevertheless, consideration of the differences in age distribution which exists between these two groups makes the corrected mortality among the group of persons with active tuberculosis approximately four and six-tenths times as great. Mortality from all causes among those not considered to have active tuberculosis was no higher than in the general population.

Use of Rabbits in Experimental Tuberculosis.—Rabbits were selected as the experimental animals for the present studies. Experiments were devised whereby the course of established acute miliary tuberculosis, caseous pneumonic, or chronic cavitary disease could be closely followed by serial chest roentgenograms before, during, and after treatment with various antituberculous agents. Only the observations concerning acute miliary tuberculosis are considered in this report. The roentgenograms were taken with the rabbit in the upright position, the chest against the cassette. The rabbits weighed between 6 and 8 lb. (2,722 and 3,629 gm.). Infection was produced by the injection of a saline suspension containing 0.01 mg. (dry weight) of bovine tubercle bacilli into the marginal ear vein. The virulent Ravenel strain was used in most instances but, since the Ravenel culture maintained in this laboratory is resistant to *p*-aminosalicylic acid in vitro, the virulent bovine *p*-aminosalicylic acid-sensitive strain no. 4228-4 was utilized to infect the rabbits in experiments in which the therapeutic effect of *p*-aminosalicylic acid was being evaluated. Treatment was not started until the chest roentgenogram revealed widespread miliary disease of the lungs except for the rabbits given *p*-aminosalicylic acid which were treated immediately after infection. Streptomycin, viomycin, and isoniazid were administered in aqueous solution intramuscularly. Amithiozone and *p*-aminosalicylic acid were given by mouth in gelatin capsules. The cultures of bovine tubercle bacilli used to infect the rabbits were highly virulent in the described dosage and produced a uniformly and rapidly fatal miliary disease. It is not the purpose of the present communication to make quantitative comparisons of the results obtained with different drugs, but merely to point out that effective agents may be clearly differentiated from ineffective ones in a relatively short period of time by following the serial roentgenograms of the lungs. This method may be used to furnish a preliminary rapid evaluation of the new antituberculous agents. Any drug which causes a definite clearing of previously established advanced miliary lesions in a group of five or more rabbits within a period of three to six weeks may be considered to be an effective drug in the experimental animal.

Antihistaminic Drugs Causing Personality Changes.—Schaffer observed unfavorable changes in the personality of 23 children who were treated with antihistamines for various allergic states, such as, seasonal and nonseasonal vasomotor rhinitis, asthma, and eczema. Before therapy, all of these children were well-adjusted and fitted into the family pattern without abnormal difficulty. In many instances the problem of personality change was brought to the attention of the parents by school teachers who noted a sudden or gradual lack of interest in school work, temper outbursts, crying spells, or antagonism. Medical examination revealed an apprehensive or antagonistic child. Careful questioning in each case established the onset of these symptoms after the start of the antihistaminic therapy. Symptoms of the personality changes disappeared within two or three days after administration of the offending drug was stopped. In asthma cases in which the antihistamine had been given with ephedrine sulphate and aminophylline, these drugs were given separately without producing similar personality changes, but when the antihistamines were again prescribed, the behavior symptoms reappeared.

Tubular Nephrosis in Shock.—Tubular nephrosis may be caused by any condition in which acute circulatory deficiency develops. It is not a primary disease of the kidneys, but is always secondary to grave disorders elsewhere. Hence it was once called extrarenal uremia. It is characterized by oliguria, proteinuria and the presence of casts, cells, and debris in the urine; there is retention of nitrogenous wastes leading to azotemia. The most important pathological features are degeneration and necrosis of the tubular epithelium. Two major factors are involved in the pathogenesis of tubular nephrosis: Toxins carried by the blood and lack of oxygen. The toxins may be of exogenous or endogenous origin, and the oxygen deficiency may result partly from renal vasoconstriction and partly from systemic anoxia incident to shock. Therapeutic measures must aim at counteracting the primary cause. For example, in shock resulting from intestinal obstruction, the existing strangulation or volvulus must first be relieved. Simultaneously the blood volume should be restored and hemoconcentration corrected by transfusions, but this must be done guardedly to avoid edema and cardiac embarrassment from excessive blood volume. The kidneys will not respond to diuretics or to increased fluid intake. The retention of nitrogenous wastes may be partially relieved by gastrointestinal or peritoneal lavage and by the use of the artificial kidney. The critical period is ended when oliguria gives place to polyuria.

Antimicrobial Therapy of Pulmonary Tuberculosis.—Since 1946 Tempel and associates subjected six antimicrobic agents to clinical investigation in a total of about 1,300 patients with pulmonary tuberculosis at Fitzsimons Army Hospital. The following drugs were used singly or in various combinations: streptomycin, *p*-aminosalicylic acid, amithiozone, viomycin, oxytetracycline (Terramycin), and isoniazid. Summarizing their observations on 875 patients with moderately or far advanced pulmonary tuberculosis, the authors say that intermittent streptomycin therapy equalled the therapeutic effectiveness observed when streptomycin was administered daily and there were fewer toxic effects and a lower incidence of streptomycin-resistant organisms. The combination of intermittent streptomycin and daily *p*-aminosalicylic acid administration is one of the most effective drug regimens available today. Combinations of drugs proved more effective than any antimicrobial agent used singly, and, with the exception of amithiozone and streptomycin, produced less drug resistance than either antimicrobial agent. Amithiozone proved of slight value, because it has a high degree of toxicity and low therapeutic effectiveness. Limited observations on viomycin and oxytetracycline indicated therapeutic effectiveness, and the combination of either of these agents with streptomycin nearly equalled the results obtained with the combination of streptomycin and *p*-aminosalicylic acid. A high incidence of toxicity limits the clinical use of viomycin and oxytetracycline. Preliminary studies with isoniazid were encouraging, but this drug should not be used alone, because of the high incidence of drug resistance. When combined with streptomycin this disadvantage is minimized, but further experience is necessary before this regimen can be recommended. Drug therapy is most effective against recent tuberculosis, that is, against disease that has existed for less than 6 or 12 months. The required duration of drug treatment has not been definitely established, but it is believed that treatment should be continued for from three to six months after roentgenoscopy reveals clearing and cavity closure and cultures are consistently negative. Most patients with extensive caseous pneumonic disease will require 8 to 12 months of continuous drug therapy. Although the results of drug therapy are often dramatic, they are not always curative, and so it should be combined with bedrest, collapse and surgical measures.

Complications of Pneumoperitoneum Therapy.—Pneumoperitoneum therapy has gained wider use in the nonsurgical treatment of tuberculosis. This is exemplified by the increasing number of patients subjected to this treatment in the New York Municipal Sanatorium during the years from 1947 to 1951, inclusive. During this period, 472 patients received a total of 24,750 peritoneum refills. Observations on this number of patients indicated that there is no question of the therapeutic value of this method, but it was also observed that complications develop in a considerable number of patients. Thoracic complications included mediastinal emphysema, pneumothorax, bronchial obstruction and atelectasis, and pulmonary collapse. Complications due to the administration of air were air embolism, subcutaneous emphysema, febrile response, and pain. Abdominal complications are as follows: adhesions, formation of fluid in the peritoneal cavity, intestinal obstruction, acute appendicitis, tuberculous and nontuberculous peritonitis. Herniation developed during pneumoperitoneum treatment in 10 patients. These included three umbilical and four inguinal hernias, and three pneumatoceles of the spermatic cord. The author also comments on six cases in which hernia existed before pneumoperitoneum treatment was started. In those in whom herniorrhaphy is done before pneumoperitoneum treatment is instituted, a wait of at least four weeks will be necessary and the pneumoparitoneum treatment will have to be made with special caution. There were four patients in whom edema of the lower extremity developed. The author feels that pressure exerted on the pelvic veins is probably the explanation of this edema. While some of the complications arising from pneumoperitoneum are mild, others are serious, and for this reason the indications for pneumoperitoneum treatment should be considered carefully.

Mucocele of Lung Due to Congenital Obstruction of a Segmental Bronchus.—The case reported was that of a 15-year-old girl, in whom tuberculosis was diagnosed on the basis of a positive gastric culture, previous contact with active tuberculosis, and symptoms of weakness, easy fatigue and feverishness. With the exception of the rounded density in the region of the apex of the lower lobe on the left side, the pulmonary infiltrations decreased considerably. It was believed that the rounded lesion should be removed, the tentative diagnosis being either a congenital bronchial cyst with associated tuberculosis, or pulmonary tuberculosis with cavitation in the left lower lobe. Operation disclosed filmy adhesions between the superior and posterior segments and the adjacent wall. The lung was abnormal in that the basal segments were dividid into two portions by a long vertical fissure. There was a partial fissure between the superior segment of the lower lobe and the basal segments; the interlobar fissure was incomplete, being totally absent in the posterior half; the bronchi of the posterior segment of the upper lobe originated from the subsegmental bronchus of the superior segment of the lower lobe and traversed the posterior portion of the usual fissure line. Dissection revealed a smooth, rounded, pale, semitranslucent cyst-like dilatation of the bronchial system. When an occasional branch was ruptured during the dissection, it was found to contain a large amount of thick, whitish mucoid material. A triple resection of the left lung was performed. The superior segment of the lower lobe and the posterior segment of upper lobe were removed together. A subsegment of the superior lingular segment of the upper lobe was removed separately, because of a tuberculous lesion at that point. The convalescence was uncomplicated. The author feels that this mucocele of the lung seems to provide the "missing link" between bronchial cyst and congenital bronchiectasis. The case suggests that pulmonary blebs, bullae, pneumatoceles and perhaps emphysema arise from disturbances in the collateral ventilation of the lungs.

Clinical Significance of pH of Ophthalmic Solutions.—Floyd and associates list the following as the essential requirements of ophthalmic solutions: pharmacological effectiveness, freedom from irritation, stability, and sterility. In some instances it is difficult to meet all four requirements, principally because a vehicle or a pH which is optimal from the standpoint of pharmacological effectiveness may be undesirable from the standpoint of stability. Besides, there arises the question to what extent the greater effort and cost connected with the preparation of accurately buffered solutions is justified by greater pharmacological effectiveness. The authors reinvestigated the problem with more accurate methods of measurement. Pilocarpine seemed to be the logical drug for such a study, which consisted of measurements of the horizontal pupillary diameters of human eyes under the influence of topically applied drugs. The patients selected for the study had normal eyes except for the presence, in some cases, of early stages of senile cataract, or of healed choroiditic or other posterior segment lesions. The anterior segments were free of congestion or irritation. The light reflex and the near reaction of the pupils were normal. The measurements were made in a dark room with a slit lamp in which the illuminating system had been replaced with the microscope lamp. The preliminary tests revealed an individual factor as well as a dependence of the degree of miosis upon the initial width of the pupil, the change in pupillary width under the influence of a miotic drug being more pronounced in eyes with initially wide pupils and vice versa. There was evidence that vehicles of near-physiological pH are of no decided clinical superiority over more acid vehicles unless the acid vehicle offers a strong resistance to neutralization. The greatest differences in drug effect attributable to the vehicle amount to about 12% of the mean, which is probably equivalent to a reduction in the effect of pilocarpine from that of a 1% to that of a 0.75% solution. Under conditions of clinical practice where the usual dose of a drug solution is about two drops, even a highly neutralization-resistant vehicle does not appreciably interfere with the action of the drug. All observations recorded here are compatible with the view that the buffer capacity of the tears is highly effective in adjusting the pH of a drug solution. This natural process of adjustment probably favors the absorption of most of the alkoloids commonly used in ophthalmology.

Hematocrit and Hemoglobin Response of Blood Donors.—The removal of one liter of blood significantly reduced the interval of useful consciousness when oxygen was withdrawn at 35,000 ft. simulated altitude. When, during the latter part of 1951, Air Force personnel were requested to make blood donations to the Red Cross program, the question arose: should flight personnel be grounded following such donation and if so, for how long? Hematocrit and hemoglobin studies were carried out for 28 days posthemorrhage on 11 men who made blood donations. The average fall in hematocrit in this group was 11.7% and the average hemoglobin fall was 13%. The time at which the minimum values occurred varied among subjects, but was predominantly between the second and sixth day. Multiple studies were made on three subjects, one of whom gave three donations without complete recovery between. In each case the minimum period for both hematocrit and hemoglobin appeared between the second and third week after bleeding. These studies did not give clear evidence favoring grounding of a flyer for a period after a blood donation. While a high correlation exists with hypoxia tolerance, it is apparent from the data presented that the normal variation in hemoglobin between subjects is greater than the change induced in a subject in 8 of the 11 cases. Hemoglobin concentration, however, is not a fundamental index of individual fitness or performance.

Transplacental Transmission of Western Equine Encephalomyelitis.—Shinefield and Townsend review evidence of transplacental transmission of antibodies and viruses, and describe histories of 5-day-old twin girls observed during an epidemic of Western equine encephalomyelitis. The infants were delivered in a hospital and were discharged with no apparent abnormality four days later. Twenty-four hours later one of the twins showed symptoms suggestive of Western equine encephalomyelitis, and 12 hours later, the other twin showed similar symptoms. They were readmitted to the hospital with a probable diagnosis of meningitis, and intensive chemotherapy was instituted. Clinical improvement was observed on the seventh day, and the infants were sufficiently improved for discharge on the 13th day. Serologic tests indicated that the infants had had Western equine encephalomyelitis. Interrogation of the mother disclosed that she had had feverishness, headache, and lethargy on the day before delivery, and that nine days previous to that she had been severely bitten by mosquitoes in the region in which Western equine encaphalomyelitis had been prevalent. Twenty-three days after her illness the complement fixing antibodies in her serum were present in a titer of 1:128. Evidence strongly suggests transplacental transmission of the virus. During the same epidemic two other pregnant women with clinical and serological evidence of encephalomyelitis were observed, the onset of their illness being within three days of delivery. The infants in both cases showed neither clinical nor serological evidence of the disease either at birth or at two months of age. Apparently, maternal infection with Western equine encephalomyelitis in the late stages of pregnancy does not invariably infect the infant. Infection in utero may depend on local placental defects.

Oxytetracycline (Terramycin) in Treatment of Diphtheria.—Lall and Karelitz gave oxytetracycline (Terramycin) in doses of 50 mg. per kilogram of body weight per day to six patients with acute diphtheria and to six diphtheria carriers. Patients with acute diphtheria also received diphtheria antitoxin. The contact carriers were treated with oxytetracycline only. It was found that, when given along with antitoxin, oxytetracycline is effective in acute cases of diphtheria. The administration of oxytetracycline alone rapidly eliminated Corynebacterium diphtheria from the nose and throat of contact carriers. Oxytetracycline like chlortetracycline (Aureomycin) may be given to diphtheria patients who are allergic to penicillin or who harbor bacterial strains resistant to penicillin.

Spinal Injection of Blood to Lower Blood Pressure.—According to Heimark and Parsons many hypertensive patients who sustain a severe cerebrovascular accident and survive eventually develop a normal blood pressure. The cause of this reduction in blood pressure remains unexplained. The authors introduced blood into the spinal canal of patients with hypertension. One of the authors performed the spinal puncture, while the other withdrew the blood from the arm and injected it into the spinal canal. At no time was the spinal fluid observed to be discolored from the previous blood injection; neither did there appear to be any increase in the spinal fluid pressure. Each blood injection seemed to be as nondisturbing as a spinal puncture for diagnostic purposes. The first injection in each case consisted of 1 cc. At the second injection the amount injected was again 1 cc., but at later injections 2, 4, or 5 cc. was injected. The first patient was given four and the second was given five injections. The blood pressure readings taken on the days of the injections are listed. Besides reductions in pressure, the bounding pulse subsided, and there was lessening of nervous tension. The authors believe that their experience indicates the desirability of further research with this method.

Lobotomy and Epilepsy.—The occurrence of convulsive seizures after prefrontal lobotomy is a serious problem. A total of 622 patients subjected to prefrontal lobotomy were followed for a minimum of two years and some for more than 15 years. A group of 498 patients treated by transorbital lobotomy was included in the study for comparison. All patients who had seizures were included in the statistics, even if the convulsions were observed only in the immediate postoperative stage. The lowest percentage was obtained in patients operated on only once, with no complications, and free from preexisting brain disease or epilepsy. This figure was 19% for prefrontal lobotomy and 1% for transorbital lobotomy. The highest incidence was in seven patients with both preexisting brain disease and operative complications, lobotomized two or more times. Six of these seven patients had seizures. There was only one such patient in the transorbital series and no convulsions have been reported yet. From these figures it may be concluded that the extent of damage to the cerebral cortex is the outstanding factor in the development of convulsions. In general, the closer the incisions come to the motor cortical centers, the more likely the patient is to have postoperative epilepsy. In this respect the transorbital operation is safer. Postlobotomy convulsions can be controlled in about 60% of cases; thus they differ little from other post-traumatic epileptic states. Advancing age lessens the incidence of seizures. Men are more likely to have seizures after lobotomy than women. Patients with convulsions have a lower level of social achievement than those who do not, but a fair number, 43 of 150 patients with seizures, are able to maintain themselves in a useful mode of life after lobotomy. Quiet patients are somewhat more apt to have seizures than violent patients. The only paradox in this study was the finding of 11 patients who had a history of convulsive seizures before operation, but not after. Allowing for errors in observation and too short a period of follow-up, there still remains the likelihood that a change for the better in the emotional status of the disturbed patient may also bring about a change in the physical, chemical, and electrical components in total behavior that may reduce the incidence of seizures.

Drug Resistant Organisms During Treatment with Isonicotinic Hydrazides.—Coates and associates studied the clinical course of 43 patients under treatment with the hydrazides of isonicotinic acid, 27 receiving isoniazid and 16 iproniazid. Particular attention was given to the emergence of drug resistant tubercle bacilli. The patients were a selected group, mostly with far advanced chronic, cavitary tuberculosis. Increased bacterial resistance to isoniazid or iproniazid appeared as early as the fourth week of therapy, and by the 14th week 80% of the group yielded cultures showing increased resistance in vitro. Loss of drug effect, as indicated by reversion of sputum bacillary counts to previous high levels, or by unfavorable roentgenographic changes, occurred during therapy in 28 of 43 patients. In most cases such an event was preceded by, or coincidental with, the appearance of drug-resistant organisms in the sputum. The appearance of bacilli in the sputum with only slightly increased drug resistance may be associated with roentgenographic or bacteriological evidence of loss of drug effect. General clinical improvement, which was striking in most cases, was often maintained in spite of roentgenographic or bacteriologic deterioration. The authors believe that the isoniazid drugs may be of use in conjunction with collapse or excision of cavitary disease and in combination with other chemotherapeutic agents.

Penicillin Prophylaxis of Streptococcic Disease.—Wannamaker and associates present observations made during several trials of penicillin as a prophylactic agent in epidemic streptococcic pharyngitis and tonsillitis at an Air Force base. Oral administration of penicillin eradicated group A streptococci from the throats of carriers when given in a dosage of 1,000,000 units twice daily for 10 days and was probably effective in half this dosage. A dosage of 250,000 units once daily for 10 days did not suppress or eradicate the carrier state in many men harboring these organisms. A single intramuscular injection of 600,000 units of procaine penicillin in oil failed to eradicate group A streptococci, but four similar injections administered every other day were effective in almost every case. Benzethacil (dibenzylethylenediamine penicillin G) given as a single injection of 600,000 units or two simultaneous injections totaling 1,800,000 units successfully eradicated the carrier state. The streptococcic disease rates and carrier rates were reduced for two or three weeks in large groups of men who received 1,000,000 units of penicillin by mouth twice daily for 5 or 10 days. It is suggested that short-term intermittent administration of a bactericidal drug such as penicillin may be an effective method for the prophylaxis of streptococcic disease and may have certain advantages over the continuous exhibition of suppressive agents such as the sulfonamides. During times of emergency large quantities of penicillin may not be readily available, in which case sulfadiazine may be employed for prophylaxis and penicillin used for treatment of streptococcic infections.

Intracardiac Puncture in Cardiac Arrest.—Cronkhite reports on a 70-year-old woman who was seized by a substernal oppression and irregular heartbeat two days before admission to the hospital. She felt as though she were going to faint. These symptoms recurred several times during the day and were usually accompanied by vomiting. Each episode lasted from 3 to 10 minutes. On the next day she lost consciousness twice after experiencing the same symptoms. On the morning of admission she "fainted" seven or eight times and was seen by her physician, who sent her to the emergency ward. She stated that her blood pressure had been elevated for about five years and that for two months she had experienced shortness of breath on exertion. An electrocardiogram taken before any medication was given showed a bizarre pattern of extreme ventricular irritability, with runs of ventricular tachycardia and ventricular fibrillation. During the next 24 hours the patient experienced 23 separate episodes of complete and prolonged ventricular standstill. In each the heart was made to beat again by the introduction of a cardiac needle into the ventricular wall. No medication was introduced into the heart. During the first 12 hours efforts were made to influence the irritability of the heart by the following drugs: 0.4 gm. of quinidine sulfate by mouth, which was followed by vomiting, 1,400 mg. of procaine amide hydrochloride intravenously over a 5-hour period, 0.4 mg. of atropine sulfate intravenously and 0.4 cc. of 1:1,000 epinephrine solution diluted to 1:500,000 intravenously. None of these drugs favorably influenced the attacks of asystole. Electrocardiograms were taken of each attack during the 24-hour period. Gradually, the attacks subsided. The patient was discharged on the 10th hospital day. When seen three months later she had no cardiac symptoms. The author suggests that mechanical stimulation of the heart with an intracardiac needle, even without the use of intracardiac drugs, may prove helpful in the treatment of acute cardiac standstill.

Sudden Death in Infancy.—In this critical review of the problem of sudden death in infants Nevius stresses that it is unlikely that it is caused by mechanical suffocation. It is much more probable that some natural but unrecognized disease process has been operating. He cites observations that indicate that in about 80% of these cases some form of acute respiratory infection is the cause of death. At least a gross postmortem examination and, in addition, careful microscopic examination of all the main organs is necessary if the true cause of death is to be established. In addition, the following laboratory examinations are helpful in many cases: a blood culture, a complete blood count, and determination of the blood sugar content, carried out as close to death as possible. If not obtained prior to death, a blood culture and a lumbar puncture done post mortem should reveal valuable information.

Clinical Histoplasmosis in Pennsylvania.—Two cases of clinical histoplasmosis are described, in both of which the correct diagnosis was made before death. In one, the tissues removed from the ulcer in the soft palate showed the characteristic Histoplasma bodies in the cytoplasm of the macrophages. In the other, the histologic studies as well as the culture of the tissues and exudate confirmed the diagnosis. Where the diagnosis of histoplasmosis is suspected, reliance cannot be placed on the skin and/or complement-fixation test. Despite the extensive dissemination of histoplasmosis in the second patient, both the skin test and complement-fixation tests were negative. The failure of this patient to react to the skin test and the negative complement-fixation reaction are analogous to the phase of anergy one observes in certain cases of disseminated tuberculosis. There is no specific therapy in histoplasmosis. Evidently much depends upon the severity of the infection and the ability of the patient to combat the disease. Until more effective and specific therapy is discovered, it may be wise to advise a prolonged bed rest plus a nutritious diet as in the treatment of pulmonary tuberculosis. Histoplasmosis is probably more prevalent than the reports indicate. The presence of the organisms in soils, rivers, dogs, and rodents presents a public health problem.

Dermal Sinuses of Dental Origin.—Gurdin and Pangman point out that when a sinus occurs within the oral cavity, the teeth may be suspected as the cause, but should the same lesion occur on the skin, the dental origin may be overlooked unless the physician bears such a possibility in mind. The findings usually are skin papilla with chronic or recurrent drainage of pus and sinus formation as determined by probing or x-ray examination. If the sinus opening is not too distant from the involved dental root, the probe end may be guided to the root. A cord-like structure on intra-oral palpation that extends from the external opening to the alveolus was present in one of the three cases described in this report, and has also been reported by others. X-ray evidence of root abscess, dental cyst, or localized osteitis may be observed. Intraoral roentgenograms may show spicules of retained roots in an edentulous alveolus or a small area of localized osteitis, which might be missed in routine extraoral x-ray examination. In the first of the three cases presented a diagnosis of skin cancer had been made until methylene blue was injected into the opening of the sinus and a metal probe inserted. Dissection was carried along the probe to include all stained tissue, which was found to end against the alveolus in the region of the lateral incisor of the upper jaw. An apical abscess with granulation tissue was curetted and packed open, and healing occurred per primum. There has been no recurrence. The lesion on the cheek was mistaken for another pustule in the second patient, who had pustular acne. The third patient had had a "cyst" of the cheek for three years. Factors that may confuse the diagnosis are: the absence of a history of acute dental abscess, a negative x-ray examination, an edentulous mouth, a confusing biopsy report, and a positive bacteriological report, such as the detection of organisms belonging to the Actinomyces group. The differential diagnosis must take into consideration epidermoid cysts, salivary fistula, thyroglossal sinus, bronchial sinus, actinomycosis, and syphilitic osteitis. In the treatment, the pathological condition in the jaw must be corrected first. If a chronic apical abscess is present, the tooth should be extracted and retained root or sequestrum should be removed, and the granuloma curetted. Most sinus tracts will then close. However, if the sinus has persisted for a long time, surgical excision may be necessary. If operative procedures have been resorted to before proper diagnosis, an umbilicated scar may persist, which will require secondary revision.

Cholecystoduodenal Fistula Associated with Chronic Abscess in Abdominal Wall Containing a Gallstone. J. J. Berens, G. A. Hallenbeck and J. C. Cain.—p. 337.
*Agranulocytosis Caused by Phenylbutazone and 4-Amino-Antipyrine. J. M. Kiely and J. M. Stickney.—p. 341.

Agranulocytosis Caused by New Antirheumatic Drugs.—Kiely and Stickney present the histories of two patients in whom agranulocytosis developed after the use of the new antirheumatic drugs, phenylbutazone (Butazolidin) and 4-aminoantipyrine. The granulocytes were the only element of the blood affected. In each case approximately two months of continuous administration of the drug preceded the onset of agranulocytosis. Recovery after withdrawal of the drug was prompt. The hazard of this serious complication must be considered when drugs are used, which are chemically related to aminopyrine. When drugs are introduced, the statement often is made that they are without hematological effect. While that statement may be true for the 100 cases that the reporter is accounting for, he has no right, on the basis of comparatively few cases, to infer that the drug does not have any effect on the bone marrow. It requires observation of many thousands of cases to determine whether or not the marrow will be seriously affected. A review of the history of the sulfonamide drugs shows that as each drug was discovered, each was said to be without effect on the blood, and yet it took only a few months before reports appeared of granulocytopenia, thrombocytopenia, hemolytic anemia, and many others. This same is true of chloramphenicol, which has been known to produce aplastic anemia. The difficulty is that with a drug such as chloramphenicol, the reaction commonly is not immediate, as it is in granulocytopenia, but rather the reaction and its recognition are far removed from the time of administration of the drug. In the administration of any new drug we must always think of the possibility of some effect on the bone marrow and the peripheral blood.

Arterenol in Treatment of Shock.—The primary and most satisfactory approach to the treatment of shock consists of blood, plasma, and/or fluid replacement therapy, lowering of the head, and measures directed to correct the cause of the shock. Although these measures when used properly have been satisfactory in most cases, there are patients in whom the shock state persists with subsequent death. Various sympathomimetic drugs have been used when measures aimed at expanding blood volume failed. The most promising of these is arterenol, which unlike epinephrine, has an almost pure vasopressor action without subsequent vasodilatation and very little cardiac-stimulating effect. Skelton and associates administered arterenol intravenously to 47 patients in shock who did not respond to other measures. A satisfactory pressor response was obtained in 45 patients. There was an immediate pressor response. Pressures can be maintained at desired levels, but there is a rapid loss of effect after discontinuing the drug. Arterenol is safe for use in the presence of cardiovascular disease and it has no detrimental effect on the cardiac rhythm. The underlying cause of shock must be corrected, even after it has been successfully combated by artificial means.

Mammary Sarcoma.—The malignity of sarcoma of the breast depends on its histological type. It may be comparatively benign or highly malignant. Its prognosis is generally better than that of mammary carcinoma; certainly, it is much better than that of sarcoma localized elsewhere in the body. Sarcoma is suggested by a tumor in the breast which develops rapidly, attaining a considerable size within a short time; which is free in relation to the lower planes and adheres to the skin only when ulceration is impending; and which is not accompanied by regional lymphatic involvement except in the case of lymphosarcoma, in which the lymph nodes may be greatly enlarged. Certain types of carcinomas may present these same characteristics, however, and the diagnosis must always be confirmed by biopsy. Metastasis takes place chiefly by way of the bloodstream; the tumors are highly vascular and intense capillary proliferation accompanies their rapid growth. The newly formed vessels offer little resistance to the sarcoma cells, which readily pass through the endothelial barrier and are rapidly disseminated by the blood. Lymphatic spread is rare by comparison, except in lymphosarcoma. Local recurrences are frequent, but do not prevent final recovery; follow-up of one patient with three recurrences in two years showed that she was alive and well seven years after her last operation. Sarcomas are radioresistant, but postoperative radiotherapy appears to lessen the danger of local recurrence. The rarity of this lesion is shown by the fact that, of 1,900 breast cancers seen at the anticancerous center of the University of Liège since 1925, only nine proved to be sarcomas; five of the patients are alive and well after periods ranging from two and one-half years to 27 years, two died of sarcoma, and two died from unknown causes. Radical mastectomy with removal of lymph nodes as a precautionary measure, followed by radiotherapy, is the treatment of choice.

Raynaud's Syndrome and Progressive Scleroderma.—The subject of this report, a woman of 32, was the mother of five normal children. Two years prior to her examination she had had an acute vaginal hemorrhage which lasted four days after normal delivery of her fifth child. After the hemorrhage the patient complained of asthenia, loss of weight, and constant headache. There was a partial loss of the axillary and pubic hair and of the eyebrows. Hypoglycemia, hyponatremia, a diminished elimination of the 17-ketosteroids in the urine and atrophic cells in the preparations of the vaginal secretions were observed. Diagnosis of scleroderma was confirmed by a biopsy. The lungs and the esophagus were involved by the disease. The Thorn test of induced eosinopenia failed after administration of epinephrine but was positive after administration of 25 mg. of corticotropin (ACTH). The authors call attention to the role of the anterior hypophysis in the development of the Raynaud's syndrome and progressive scleroderma. The chronologic sequence in the case was as follows: The acute vaginal hemorrhage caused ischemia of the anterior hypophysis with consequent imbalance of the hypophysiocorticoadrenal and hypophysiogonadal systems, insufficiency of cortical and gonadal hormones and the development of diffuse scleroderma and Raynaud's syndrome.

Bronchial Carcinoma.—An increase in bronchial carcinoma has become evident in many countries in recent decades. Denk states that in Vienna carcinomas of the respiratory organs account for increasingly larger percentages of the total cancer mortality. Attempts to explain this increase have been concerned chiefly with the etiological importance of tobacco, particularly cigaret smoking. Denk investigated the smoking habits of 757 among 1,145 patients with pulmonary cancer, and found that 10.8% were nonsmokers, light smokers (less than 10 cigarets per day) accounted for 30%, moderate smokers (up to 20 cigarets per day) for 30.8% and heavy smokers (more than 20 cigarets per day) for 28.4% of this number. These figures indicate a much smaller percentage than do other statistics for the heavy smokers and a comparatively high percentage (41%) for nonsmokers and light smokers. Thus the American observations that the greater the consumption of cigarets, the greater also the likelihood of the development of bronchial carcinoma does not hold true to the same extent in Austria. The author feels that possibly a different process of preparation of the tobacco or the use of different insecticides might account for these differences. The arsenic and benzpyrene content of the air in big cities likewise can be no more than a contributing factor in the increasing incidence of bronchial carcinoma. Efforts should be made to diagnose bronchial carcinoma during the asymptomatic stage, and to accomplish this men over 40 years of age should be subjected to roentgenoscopy of the chest at regular intervals. However, "silent" carcinomas are not necessarily always operable. Of 41 silent bronchial carcinomas, 9 were inoperable on exploratory thoracotomy, in 8 other cases distant metastases produced the first symptoms, 8 patients refused operation, 7 carcinomas were found unexpectedly at necropsy, and 9 patients underwent radical operation. Even if all of the 8 who refused operation had been operable, only 17 of 41 silent bronchial carcinomas would have been amenable to radical operation. Tomography and bronchoscopy are valuable aids in the diagnosis, whereas cytologic examination at the most can corroborate or weaken the results of other examinations. In deciding the advisability of surgical treatment functional tests of heart and lungs should not be neglected, because patients with coronary insufficiency tolerate pneumonectomy poorly. Of 1,145 patients with bronchial carcinoma 612 proved inoperable on the basis of clinical examination. Of the 533 subjected to surgery, 241 underwent pneumonectomy, 40 lobectomy and 252 exploratory thoracotomy. A total of 181 of the 533 operated on are still alive.

Clinical Observations on Vagotomy.—Mandl says that since 1947 he has used vagotomy routinely in a large number of patients with ulcers. The surgical mortality of vagus resection was 1% in 300 patients. He found that the operation is inadvisable in gastric ulcers, except in those located high up, near the cardia; in these latter cases it may be tried instead of a total gastrectomy. Vagotomy without gastroenterostomy produces less favorable results than vagotomy plus gastroenterostomy. Follow-up on patients with duodenal ulcer who underwent vagotomy plus gastroenterostomy are encouraging. Many observers regard vagotomy as the operation of choice in jejunal peptic ulcer or in recurrent ulcer after gastric resection. Mandl's own observations were not entirely satisfactory in these cases. It may prove possible to avoid a secondary operation in some patients with perforating ulcer, when vagotomy is added to the closure of the perforation. Vagotomy proved effective as a secondary operation in perforating duodenal ulcer but ineffective in perforating gastric ulcer. Morbidity and mortality rates were not changed by adding vagotomy to gastric resection. It is possible that vagotomy will improve the permanent results of gastric resections in a larger number of patients. In patients with inoperable gastric carcinoma resection of the vagus will control the pain and make the final stages of the disease more tolerable for the patient.

Toxoplasmosis in the Adult.—Duke-Elder and associates present the case of a man, aged 40, who had recurrent posterior uveitis of obscure etiology. Clinically it was of granulomatous type. It recurred persistently and resulted in loss of perception of light and led to destruction of the eye. Clinical, histological, and serological evidence indicated that the disorder was due to histoplasmosis. It is suggested that the disease was either congenital or acquired in childhood, and that the active chorioretinitis in adult life was due to a recrudescence of the early infection. When sections of 32 cases of granulomatous uveitis were examined, about half showed structures resembling toxoplasma forms. However, in some of the cases in which these were found, which included such conditions as post-traumatic uveitis, and Behcet's syndrome, the diagnosis of toxoplasmosis would have been highly improbable. It is, therefore, concluded that these histological appearances probably result from cellular debris or nuclear fragmentation, and that, in the absence of confirmatory serological tests, such findings have a limited value.

Vesicointestinal Fistula in Regional Ileitis.—Robinson presents three cases of vesicointestinal fistula due to regional ileitis (Crohn's disease). The condition is rare, two other writers having reported only one case each. The first of the author's three patients died on the day after the operation, but this case produced an awareness of the possibility of correct diagnosis and treatment. The three patients were men, aged 19, 44, and 22 respectively. All were referred to the author as having chronic cystitis of obscure etiology. In the first the cystitis had been thought to be due to carcinoma, in the second to diverticulitis, and in the third to an infected urachal rudiment. The significance of the less dramatic bowel symptoms had not been appreciated, although in all three contamination of the urine by bowel contents had occurred at some time. In only one case could the fistula be demonstrated preoperatively. In each case the diagnosis became obvious once the possibility of regional ileitis as an etiological factor was realized, but undue time had been spent in arriving at a correct diagnosis. In two the disease was limited to the terminal ileum, while in the third the cecum and ascending colon were also involved. The first patient was very seriously ill when first seen, but without doubt could have been saved by an exclusion operation and intravenous therapy. The other two responded to exclusion alone with complete relief of their symptoms.

Epidemic of Pleurodynia (Bornholm Disease).—This report is based on the experience obtained during an epidemic of pleurodynia (Bornholm disease) in Oxford from September to November, 1951. Britain experienced a high incidence of this disease from April until November, 1951. A total of 277 cases were collected in Oxford. The weekly rate rose rapidly to a peak in about four weeks and was followed by an equally rapid fall. The incidence was highest in young children. Spread within the family often occurred, but one-third of the cases were found to be single infections in a household. Spread within schools was not a feature of the epidemic. The incubation period varied from 1 to 18 days, with the majority between 2 and 5 days. Symptoms were diverse. The most useful single feature in diagnosis was the characteristic spasmodic nature of the pain. Pyrexia was usually present and severe headache was common. Other less frequent symptoms included vomiting, photophobia, shivering, sore throat, pain in the limbs or neck, dizziness, delirium, hyperesthesiae, and paresthesias. In seven cases benign meningitis occurred as a complication. Orchitis was a complication in 3 out of 30 adult males. Relapses, both early and late, were a characteristic feature of the outbreak. Viruses pathogenic for infant mice were isolated from the feces of 6 out of 17 patients examined. Attempts to isolate the virus from cerebrospinal fluid, blood, and throat washings failed. The strain of Coxsackie virus isolated was identified as belonging to Dalldorf's group B. Paired serums of the acute and convalescent periods were obtained from 13 patients and tested for the presence of neutralizing antibody against the Oxford virus. A marked rise in neutralizing power in the convalescent serum was demonstrated in eight patients, while the other five cases had a high titer of antibody in both serums. Preliminary cross-neutralization tests, using the Oxford virus, indicate that it may be a previously unrecognized antigenic type.

Isolation of Coxsackie Virus from Two Patients with Epidemic Pleurodynia.—In the summer of 1951 southeast Scotland experienced an outbreak of epidemic pleurodynia (Bornholm disease). The two children whose cases are described were not specially selected except in so far as they were quite typical of the group. The disease was characterized by the sudden onset of severe intermittent pain in the upper abdomen, a short recrudescent course ending in a complete recovery, and no evidence of an underlying pulmonary lesion. No sign of meningeal involvement was present either in the 2 children investigated or in the 16 other members of the group. A Coxsackie virus of Dalldorf's group B was isolated from the feces of these two children. A rise and fall in the titer of antibodies in the patients' serums indicated a recent infection with this virus. Epidemic pleurodynia may present a variable clinical picture, with meningitic or myalgic symptoms predominating. It is possible that different strains of virus are associated with different clinical features, and that the Oxford epidemic was caused by a virus differing from that current in Manchester or Edinburgh. It is also well known that the same virus may cause both myalgic and meningitic illness. The understanding of the epidemiology of pleurodynia, of aseptic meningitis, and of nonparalytic poliomyelitis may be expected to advance rapidly when more strains of the Coxsackie virus are isolated and their immunological characters are identified.

Poliomyelitis in Canadian Eskimos.—The outbreak of poliomyelitis that occurred amongst Eskimos living in a small, far northerly settlement of Chesterfield Inlet, N. W. T., in February, 1949, was so unusual in respect of the high rate of attack and the epidemiological features that it seemed to be worth while to analyze the antigenic structure of several strains of virus isolated from patients. Five strains have now been typed, and all strains have been found to belong to type 1. They were isolated from brain and cord, stool, or throat washings. From the results of the typing tests, it may be concluded that this outbreak was caused by a single antigenic type, the type responsible for the majority of epidemics of poliomyelitis on the North American continent. The peculiar characteristics of the Chesterfield Inlet outbreak cannot be attributed to the emergence of an unusual antigenic type of virus, but rather to the operation of some factor that affected the susceptibility of the Eskimos to invasion by poliomyelitis virus. In this connection Sabin has suggested that the high paralytic attack rate may have been a reflection of the genetic constitution of the inbred population. The typing of the Eskimo strains of virus presented difficulties, because they were of a low degree of pathogenicity to monkeys by the cerebral route, but the technique of tissue culture proved particularly suitable. Its advantages include speed and low cost. Furthermore, it can be carried out in laboratories where facilities for the care of monkeys are limited.

Trichinosis: Examination of Human Diaphragms.—Bourns studied diaphragms of human cadavers collected at three Vancouver hospitals. These tissues were examined by direct compression and digestion techniques. The compression method consisted of an examination of 1 gm. of tissue, which was teased apart, squeezed between glass plates and inspected under the microscope. The second technique involved digestion of 10 gm. of chopped muscle in 0.2% solution of pepsin in 0.01 molar hydrochloric acid, and subsequent use of a Baermann apparatus. In each case, the bottom 30 cc. of digest residue was drawn off and examined under the microscope. Of 400 diaphragm specimens examined, 16 or 4% were found to contain Trichinella cysts. This figure remained consistent throughout the survey inasmuch as the successive groups of 100 contained 4, 3, 4, and 5 positive tissues, respectively. The author stresses the desirability of a control program involving public education with reference to the cooking of pork, and secondly, a program of close inspection of hog feeding and rodent control.

Lipoma Syndrome in Sacral Region: Pathogenesis of Backache.—Complaints of backache are frequent, but treatment is often unsatisfactory because the etiology is obscure in many cases. This report is concerned with the pathogenesis and differentiation of a type of backache that in Germany so far has not been recognized as a separate entity. The essential characteristic of this type is the presence of nodular lipomas in the sacral region. The disorder has been designated as lipoma syndrome in the sacral region, the lipoma being the most characteristic sign, although there are a number of other symptoms. The nodular lipomas can be detected by careful palpation. They may even be visible as cherry sized protuberances. Their consistency is dense but elastic. Pain usually increases gradually, and is almost never limited to the region of the nodules, but radiates into the back and even into the shoulder and leg. The pain may be drawing, piercing, or tearing in type. Certain movements, particularly bending or turning in the hips, intensifies the pain. Housewives often complain that the pain is greater on wash-days or on days they do ironing or similar tasks. The nodules are usually found alongside of the lateral limits of the rhomboid of Michaelis. This type of backache is rather frequent. Among 150 patients who complained of backache, there were 72 in whom lipomas in the sacral region seemed to be the only cause; 57 of the 72 were women. Most of them were between the third and fifth decade. The differential diagnosis must consider sciatica, prolapse of a vertebral disk, spondylosis, lumbago, muscle rheumatism, fibrositis, and renal disease. Several typical case histories are described. Measures like inunction, application of heat, baths, and irradiation with short or ultrasonic waves all failed. Injections of 1% procaine hydrochloride solution or of similar drugs proved more effective. Injections are made underneath the lipomas, two or three times per week. If a total of six injections has produced no improvement, surgical treatment consisting of removal of the nodule is advisable.

*Estrogen Substances in Treatment of Carcinoma of Prostate Gland. A. Francese.—p. 138.
*Phosphorus Combined with Vitamin B_1 in Therapy. G. Ronconi.—p. 144.

Estromenin in Treatment of Prostate Carcinoma.—Estromenin (4,4-dimethoxy-α-α'-diethylstilbene) was used to treat 30 patients with carcinoma of the prostate gland. At first one injection of the preparation was given every three days or every five days until the patient's breasts had become tense. Three to four injections were, as a rule, sufficient to achieve this effect. This tenseness was maintained thereafter by administering the preparation at an interval of 8, 10, 15 or even more days. An optimum concentration of Estromenin has been reached when the patient's breasts have become tense. This concentration inhibits the growing process of the carcinoma without causing side-effects. Some of the patients were treated for as long as 2½ years. The general condition of many was improved, urinary frequency and dysuria diminished, and a more elastic consistency of the prostate gland was obtained. Five patients in whom metastases had developed to other organs died during the treatment. Side-effects were always very mild and consisted mainly of nausea. A comparative study revealed that this preparation gives better and longer-lasting results than the common estrogens.

Phosphorus Combined with Vitamin B_1 in Therapy.—Phosphorus in a form easy to be assimilated (Benzofosfan I.C.I.) was combined with vitamin B_1 and was given to nine patients by either the intramuscular, the intravenous, or the oral route. This combination was the only medication for one asthenic and debilitated patient, who could not maintain an upright posture because of a pronounced imbalance secondary to a trauma of the skull; one patient with gastritis due to hypoacidity; two patients convalescing from a prolonged bronchopneumonia and pleurobronchopneumonia; one patient with hypochromic anemia who was debilitated from overwork; and one patient with pyloric stenosis secondary to an ulcer. The last-named patient was not benefited from the therapy and had to undergo surgery. All the others improved and regained appetite and strength. The patient who could not stand up was able to walk after 15 days of therapy. She had received 20 intravenous injections of the preparation. Phosphorus combined with vitamin B_1 was given as an adjuvant to one patient with dyskinetic colitis and neurovegetative dystonia; one patient with chronic myocarditis who was in very poor general condition; and one patient with hyperthyroidism. The therapy benefited these three patients also. The preparation was well tolerated and there were no side-effects.

*Second Attacks of Typhoid Fever. D. E. Marmion, G. R. E. Naylor and I. O. Stewart.—p. 260.

Second Attacks of Typhoid.—The impression is prevalent that an attack of typhoid confers a high degree of immunity, although recurrences may sometimes occur. Repeated exposure to infection is not common in modern civilized communities, and this may partly explain the low incidence of second attacks. The authors describe two outbreaks that occurred in a Royal Air Force unit in the Suez Canal Zone of Egypt. The population exposed in the outbreaks had been protected by paratyphoid (T. A. B.) vaccine. The first outbreak occurred in April and May, 1950. Out of 657 men at risk 84 contracted typhoid. The causative organism was Salmonella typhi of phage type J. It was considered likely that a native cook, who was found to be a urinary excretor of Salm. typhi, was the cause of the outbreak, because it ceased about 10 days after his removal from duty. However, the organism isolated from his urine was rough and could not be phage-typed. The second outbreak occurred during July and August, 1950. There were 688 men at risk of whom 235 contracted typhoid fever. The causative organism was of phage type E 1. This outbreak was explosive in character and showed two waves. Epidemiological evidence indicated that the food eaten at midday on July 12 was the cause of the primary wave of cases. Two foodhandlers who were found to be excreting the organism during the incubation period before they developed the disease were considered to be the probable source of infection of the secondary wave of cases. The outbreak ceased 10 days after their removal from duty. Of the men who were infected in the first outbreak 54 were exposed again in the second outbreak, and 11 of them contracted typhoid again. Thirty-seven of the 54 had received chloramphenicol therapy in their first attack, and 6 of these were reinfected in the second outbreak; of the 17 who did not receive chloramphenicol 5 were reinfected. The authors feel that the specific immunity conferred by an attack of typhoid is of no more than moderate degree and, in the event of reexposure to infection, recurrences are not very unusual.

An Unusual Case of Twins.—The 24-year-old woman whose case is presented had had two previous full-term pregnancies in 1948 and 1951. In July, 1952, vaginal examination revealed that the uterus was enlarged to the size of an eight weeks pregnancy and was deflected to the right by a cystic swelling in the left fornix approximately the same size as the uterus itself. The estimated date of confinement was Feb. 15, 1953. On Sept. 15, 1952, two masses of equal size were present. The diagnosis of twin pregnancy in a double uterus was made. The pregnancy continued uneventfully until Dec. 14, 1952, when the woman was admitted to hospital complaining of backache, and a small amount of clear amniotic fluid was draining from the vagina. Examination showed that the baby in the right uterus was presenting in vertex position and was engaging in the brim of the pelvis; that in the left uterus was in breech position. On Dec. 16, 1952, she commenced to have regular, painful uterine contractions. One and a half hours later a living premature male baby weighing 3 lb. 10¾ oz. (1,591 gm.) was delivered. The placenta was immediately expelled. Vaginal examination, a few minutes after the birth of the placenta, revealed a second cervix, hitherto not felt. An intact amniotic sac was present and the fetus, which at the onset of labor was in breech position, had undergone spontaneous version and was now presenting as a vertex. After 24 hours in the labor ward, there were no further uterine contractions, the fetal heart sounds were normal, and the patient was transferred to the ward. Lactation did not occur. Involution of the right uterus proceeded normally. On Feb. 10, 56 days after delivery of the first baby, the second baby was born after 15 minutes of labor pain. The baby was normal, weighing 5 lb. 15¾ oz. (2,720 gm.). Lactation was normally established. The time interval between the deliveries, 56 days, is claimed to be a world record. Several other unusual aspects of this case are discussed.

Cervical Smears in Diagnosis of Cancer.—The series of 3,000 smears reviewed here represents 3,000 patients "screened" for cancer. For the purpose of experience 139 more were examined from clinically obvious cases of cancer and treated cases of cancer. Some of the 3,000 had several smears taken but the first report was the one used in the analysis of the results. If the first report was incorrect, even if subsequent ones were correct, it was regarded as an error and was listed as a false negative or positive. The only exceptions were occasional cases in which the first smear was atypical with possible abnormal changes, and further smears were requested. Thirty-three unsuspected cervical cancers were discovered, an incidence of 1.1%. Of 50 early cancers of the cervix encountered, 5 were missed, 4 of these in the first 1,000 and only one in the next 2,000 cases. Only one false positive report was given for cervical cancer in the last 2,000 cases. Only one unsuspected endometrial cancer was found; all the other patients would have been subjected to curettage irrespective of the report on the smear. Of 21 endometrial cancers, 12 were missed, an error of 57%. It must be emphasized, however, that it was cervical cancer that this work was designed to discover. Five patients only, of the last 2,000, had suspicious smears in which the final decision has not yet been made; five others had smears short of suspicion and are being followed. Accuracy of interpretation can be gained by long and careful study, but the results indicate that the study of cervical smears is helpful in the diagnosis of early carcinoma of the cervix. The clinician needs little assistance in the diagnosis of endometrial cancer, and its picture is difficult to interpret in smears, except in the cases in which the far more accurate curettage has already been considered essential. Cytological interpretation is most important in the discovery of early cancer of the cervix, before it is clinically obvious. Eighty per cent of these unsuspected cases were of the preinvasive or latent type, now more or less generally accepted as true cancer. In spite of the other 20% being early invasive cancers the authors doubt that the use of cervical smears as a routine gynecological outpatient procedure would be justified, were it not for the preinvasive or latent lesion.

Vomiting of Pregnancy: The Allergic Factor.—The relationship of adrenocortical insufficiency to allergy is outlined. This relationship is particularly important in the causation of hyperemesis gravidarum. In August, 1951, the authors accidentally discovered that the administration of the synthetic antihistamine compound antazoline (Antistine) to two patients with hyperemesis gravidarum, produced dramatic improvement, although adrenal cortex extract had had no effect. The authors studied the effect of antazoline on women with pernicious vomiting of pregnancy. In 5 of 28 women studied hospitalization, suggestion, and reassurance were sufficient; in these cases, the vomiting was presumably of neurotic origin. In 17 patients in whom the condition either showed only slight improvement on hospitalization, reassurance and dietetic regulation, remained stationary or got worse, complete cure was accomplished either by antazoline alone or when followed by desoxycorticosterone acetate for three days. In some of these 17 cases later recurrences were again controlled by the same treatment. In the remaining six women neither a neurotic nor an allergic cause could be found. The authors emphasize that the combination of antiallergic drugs with adrenal cortex extract gives dramatic results in the treatment of allergic hyperemesis.

Malignant Hypertension.—Heptinstall gives an account of the varied pathological conditions encountered at autopsy in a consecutive series of 51 cases of clinical malignant hypertension. No selection of cases was made, except that only those that had shown a considerable degree of hypertension and papilledema in life were included. The condition was usually associated with terminal renal failure, but in certain cases a cerebral or cardiovascular accident anticipated this event. Twenty-five of the 51 patients had essential hypertension, 8 had chronic pyelonephritis, 10 had chronic glomerulonephritis, 1 had polycystic kidneys, 3 had toxemia of pregnancy, and 4 had polyarteritis nodosa. None of the patients with essential hypertension was less than 35 years of age, patients in the younger age groups all having secondary hypertension. The blood pressure was uniformly high in all groups, the diastolic pressure being almost invariably over 130 mm. Hg. Vascular necrosis was present in those with secondary as well as in those with essential hypertension. Some cases showed vascular necrosis in the absence of impairment of renal function. Thus renal insufficiency is not a necessary factor in the production of these necrotic lesions. The severe degree of hypertension appears to be the cause of the common picture of vascular necrosis in the various groups described, irrespective of the way in which the hypertension was brought about. The fact that a variety of conditions known to cause heightened blood pressure can produce the clinical picture of malignant hypertension with vascular necrosis is evidence in favor of the theory that *the difference between the benign and malignant forms of hypertension is one of degree of* hypertension attained.

What Is Ulcerative Colitis?—Brooke discusses the reasons why the cause of ulcerative colitis has never been completely explained. *The colon can be affected by three distinct conditions: ulcerative colitis, ileocolitis, and proctosigmoiditis, all of which are customarily diagnosed as "ulcerative colitis."* The author suggests that ulcerative colitis is not a specific disease but a pathological state. The causes are to be looked for in numerous conditions that initiate in the colon the degenerative process that is ulcerative colitis. If the original trauma is severe, the case will pass directly into one of ulcerative colitis with continuous, though possibly abated, diarrhea without remissions. If healing with degenerated epithelium takes place, a latent interval, or "remission" will occur between the initial injury to the colon and the onset of ulcerative colitis; this form will be marked at first by remissions but later is likely to become chronic, with persistent diarrhea. In many instances the colon heals perfectly after damage by infection, stress, chemical agents, or whatever the cause may be; the patient is then spared from ulcerative colitis. The ileum is involved in ulcerative colitis as a secondary phenomenon, either when the ileocecal valve has become incompetent or, after operations that include an ileostomy, because of technical defects at the ileal stoma. Commenting on the relationship between regional ileitis (Crohn's disease) and ulcerative colitis, the author states that although the ulceration in regional ileitis may be widespread throughout the colon, it in no way resembles that of ulcerative colitis. Furthermore, regional ileitis more commonly attacks the ileum, and it has been stated that the association of ileal lesions with ulcerative colitis is only incidental. It therefore seems unlikely that the two conditions are of the same origin; their only similarity is that in regional ileitis the colon may become ulcerated and the diarrhea can be so severe that it simulates ulcerative colitis.

*Acute Hepatitis in Children. H. Niemeyer, O. Danus and O. Undurraga. —p. 82.
Infections by Coxsackie Virus. M. Rodríguez Leiva.—p. 91.

Acute Hepatitis in Children.—In a period of three years, 65 children with acute hepatitis were observed in a pediatric hospital of Santiago, Chile. The majority of the patients were between the ages of 1 and 4 years. In about half the number there was a history of contagion from contact with patients with virus hepatitis, 20 or 70 days in the past, or by transfusion 70 or 100 days prior to the appearance of the symptoms. The preicteric stage was very marked in 61 patients. It lasted from two to four days, with symptoms of a general infection, anorexia, weakness, fever and gastrointestinal disorders. The icteric stage was manifested by bile pigments in the urine, acholic feces, and the appearance of jaundice in the conjunctivas and on the skin. Jaundice was moderate in the majority of cases and acute in some. Predominant symptoms in this stage were those of marked hepatomegaly in all the 65 patients, jaundice in 64, and splenomegaly in 13 patients. There was a case of the nonicteric type in which the clinical diagnosis was confirmed by the presence of great hepatomegaly and bilirubinemia, the results of the tests of flocculation and of the biopsy of the liver. In all the patients, hepatomegaly persisted through the icteric and posticteric stages and regressed very slowly. A biopsy of the liver was made in some of the patients in whom the structure was of very hard consistency. It showed changes which varied from moderate granular degeneration to early fibrosis of the liver.

*Use of Massive Doses of Vitamin B_{12} in Neurology (1,000 Micrograms per Injection). J. Lereboullet and R. Pluvinage.—p. 1849.
Rheumatic Conditions of the Shoulder. S. de Sèze, J. Debeyre and A. Denis.—p. 1855.
*Mechanical Endobronchial Method of Increasing Bacillary Content of Sputum in Tuberculosis Not Bacteriologically Evident. M. Fourestier and J. Marsault.—p. 1871.

Massive Doses of Vitamin B_{12} in Neurological Conditions.—Appropriate vitamins given in small doses have a specific effect on deficiency states; given in much larger doses, they have proved curative in many conditions in which no known deficiency exists. Increasing supplies of vitamin B_{12} have made possible its use in larger doses with consequent extension of its sphere of action. The blood picture in pernicious anemia was not only improved more rapidly and effectively by the use of large doses of this vitamin but regression of the nervous lesions was also secured even in bedridden patients in whom they had apparently reached an irreversible stage. Equally significant results have been obtained in other forms of neurological disturbance, such as certain types of multiple sclerosis, the polyneuritic and psychic complications of alcoholism, syndromes in the subacute superior polioencephalitic group, and essential facial neuralgia. Vitamin B_{12} is apparently entirely nontoxic and no complications resulting from its use even in doses of 1,000 mcg. have yet been reported. Its basic antipernicious effect probably comes from direct intervention in the biochemical processes of red cell maturation; its other effects are presumably the result of indirect or substitutive participation in the enzymatic processes, especially those involving the functioning of the nervous system.

Endobronchial Method of Increasing Bacillary Content of Sputum.—Diagnostic difficulties caused by the inability of hospital and dispensary laboratories to meet all the requests received for cultures and inoculations in doubtful cases of tuberculosis led to the development of an endobronchial method of increasing the bacillary content of sputum. The suspected area is examined bronchoscopically after anesthesia of the rhinopharynx, larynx, and trachea; interrupted aspiration (30 seconds in all; 10 seconds at a time) is then carried out through a flexible rubber cannula introduced as far as possible into the lobe or the segment under visual control and without any additional local anesthesia; and 5 cc. of isotonic sodium chloride solution or distilled water is injected into the bronchus through the cannula to produce a mild irritation (indicated by the patient's coughing). The effect of the irritation is to remove a possible bronchial obstruction and to cause a minimal focal reaction that results in the easier discharge of bacilli from the lesion through the bronchial passages. Bacteriological examination of all sputum spontaneously produced in the four days following the procedure will furnish proof of tuberculous disease in more than 50% of the patients whose response to the usual tests is negative. The procedure, known as "four day K.B.," is perfectly safe; the patients are usually in excellent condition, without functional respiratory disturbances, and tolerate bronchoscopy perfectly.

*Bornholm Disease, Pleurodynia or Epidemic Myalgia: Outbreak in the Transvaal Associated with Coxsackie Virus Infection. I. M. Patz, V. Measroch and J. Gear.—p. 397.
*Hypotensive Anaesthesia in Plastic Surgery: Report on 500 Cases. H. Bentel and J. Penn.—p. 405.
ACTH and Epileptiform Seizures in Childhood: Preliminary Report. A. C. Watt and S. Jacobson.—p. 407.

Epidemic Pleurodynia and Coxsackie Virus Infection.—The author reports an epidemic of an illness characterized by signs and symptoms of epidemic pleurodynia (Bornholm disease), which occurred in Middelburg, Transvaal, during the latter half of January and the first week of February, 1952. The epidemic involved children living in a school hostel. Of 180 children in the hostel, 40 became ill. The onset was sudden; most of the children had acute epigastric pain and tenderness often associated with severe headache, nausea, vomiting, and fever. The fever lasted one to three days. In one-third of the cases the illness recurred and in one-tenth of the cases a second relapse occurred. Abdominal signs and symptoms predominated. In five adults chest symptoms were more prominent. Laboratory studies revealed that this illness was associated with an infection of a Coxsackie group B type 4 virus. In addition to being pathogenic to and producing characteristic lesions in baby mice, this virus was also pathogenic to adult mice, causing in some an extensive destruction and inflammation of the pancreas. Involvement of the pancreas in human cases is possible, but no studies of pancreatic involvement were made in this outbreak. It is now becoming clear that outbreaks of epidemic pleurodynia are caused by infection with Coxsackie virus, particularly by strains of the B group.

Hypotensive Anesthesia in Plastic Surgery.—About one year ago these authors had reported their experience with hypotensive anesthesia in 100 operations, and now they report on

Dr. Robert Fleig Library
32680 [illegible] Medical College

a total of 500 cases. Vomiting occurred in less than 10% of the cases, possibly because hexamethonium retards the motility and secretomotor activity of the stomach. Very little ether is required once hypotension has been produced. The average postoperative recovery period was 10 to 15 minutes after completion of the operation. After the patient has been put on the table it is tilted into a reverse Trendelenburg position of 10 to 15 degrees in older patients, and up to 35 degrees in younger ones. A Gordh needle is then inserted into a vein and the hexamethonium injected. The dose varied from 40 to 80 mg. in young, healthy adults, to 10 to 25 mg. in the elderly or hypertensive patients. The authors discuss the use of intubation, 100% oxygen and other measures important in this form of anesthesia. Other reports on hypotensive anesthesia state that a systolic blood pressure of 70 mm. Hg is adequate from the point of view of the surgeon. This was too high in this series of cases, possibly due to the altitude of Johannesburg (5,800 ft.). With hexamethonium, the optimum blood pressure level in Johannesburg was found to be approximately 60 mm. Hg in hypertensive and older patients, and 50 mm. Hg in young, healthy adults. The method is used only on patients regarded as being normal anesthetic risks. Controlled hypotension was not used for longer than 1½ hours. When an operation required longer anesthesia, controlled hypotension was utilized only for the essential stage in that operation, after which the pressure was allowed to rise to 80 or 90 mm. Hg. Almost every type of plastic operation "above the belt" has been performed under hypotensive anesthesia. It ensured an even, rapid technique, reduced trauma and afforded a smoother convalescence with a minimum of edema and pain in the operative field. If patients are carefully selected, and if adequate anesthesia with full oxygenation is guaranteed, and if cooperation between surgeon, anesthetist and nursing staff exists, the hypotensive anesthesia is a most important advance in plastic surgery.

Partial Oxygen Pressure of the Arterial Blood in Surgical Disease of the Lungs. T.-O. Lindenschmidt.—p. 65.

Correcting Scoliosis by Plastic Spreading of Ribs.—Plastic operations on the ribs can be employed, according to Felix, in the treatment of scoliosis. Sauerbruch and his co-workers resorted to rib plication by means of wires or metal bands on the convex side of the curvature and performed a simple paravertebral division of the ribs on the concave side. The double intervention was usually done in two stages. The early results of this method were satisfactory, but the late results were not. The author used this method in 16 young patients with scoliosis and found that the initial improvement disappeared at a later date. He continued to perform plication of the ribs on the convex side of the scoliotic curvature, but tried to make it more secure by using double wires for each pair of ribs, and by tying the ribs closer with clamps. On the concave side of the scoliotic curvature Felix replaced Sauerbruch's simple paravertebral rib division by a spreading of the ribs. This spreading on the concave side is the exact opposite of the plication on the convex side. The ribs are spread apart in the paravertebral region by hook traction, and the spreading is maintained by implanting struts of bone chips into the rib interspaces. The rib plication plastic on the convex side and the spreading of the ribs with the aid of bone struts are complementary in straightening the scoliotic curvature of the vertebral column. Comparing the results obtained in 7 patients in whom this new procedure was employed with those in the previous 16 cases revealed that the combined use of plication and spreading is superior.

Pathology and Surgical Treatment of Hydatid Cyst of Lung. V. Pérez Fontana.—p. 7.
*Frequency of Cancer of Lung in Private Practice. G. Sayago and J. B. Rocca.—p. 47.
Chiari's Syndrome Due to Bronchial Neoplasm. M. Arcos Pérez, D. Tomalino and O. Muras.—p. 89.

Cancer of Lung.—The authors present analysis of 6,269 private patients who had been observed for the past 25 years. There were 2,013 patients between the ages of 33 and above 70 years. In this group, 57 (2.8%) had cancer of the lung and 10 had pulmonary metastases from cancer of the breast, the uterus, the stomach, or the testis. Patients with metastatic cancer are not included in this report. There were 56 men and 1 woman with pulmonary cancer, most of them between the ages of 33 and 50 years. The most frequent symptoms, in order of frequency, were cough, expectoration, bloody sputum or frank hemoptysis, fever, loss of weight, and chest or shoulder pain. The average duration of the symptoms before the first consultation was 10 months. Roentgen examination of the chest showed the tumor shadow in the right lung in 32 patients, in the left lung in 24, and in both lungs in one patient. In one of the patients the cancer of the lung complicated pulmonary tuberculosis. A definite diagnosis was made on the basis of clinical symptoms and roentgen signs of the disease in 21 patients. In the remaining 36 patients suspected cancer was confirmed by bronchoscopy in 17 cases (in 15 of which the bronchoscopic biopsy was also positive), by sputum cytologic study in 5 cases, by the roentgen picture of cancerous invasion of ribs in 3 cases, by a positive biopsy of a supraclavicular lymph node in 5 and of a thoracic node in one case, by microscopic study of lung tissue removed surgically in 3 cases and by the necropsies in 2. The authors direct attention to the fact that symptomatic or clinically apparent cancer corresponds to the stages of the disease. In 24 of their patients, the symptoms had lasted between one and six months and the disease was in an advanced stage. It appears advisable to practice systematic and periodical roentgen examintions of the chest in large groups of apparently healthy people to obtain an early diagnosis and surgical treatment of the condition in the preclinical phase.

*Control of Anticoagulation Therapy by Owren's Method of Quantitative Prothrombin-Proconvertin Determination. E. Lund.—p. 801.
*Long-Term Dicumarol Therapy of Coronary Thrombosis and Other Thromboembolic Disorders. E. Lund.—p. 805.
Treatment of Pernicious Anemia with Small Amounts of Pylorus Mucosa and Vitamin B_{12} and with New Combination Preparation. E. Meulengracht.—p. 809.

Control of Anticoagulation Therapy by Owren's Method of Quantitative Prothrombin-Proconvertin Determination.—Anticoagulation therapy of thromboembolic diseases is mainly preventive. The important indications for the treatment are acute coronary thrombosis, peripheral thrombophlebitis, and pulmonary embolism. One hundred patients with thromboembolic diseases, of whom 45 had coronary thrombosis, were treated with anticoagulants (heparin, bishydroxycoumarin [Dicumarol], in a few cases ethyl biscoumacetate [Tromexan ethyl acetate]) with control of the coagulating capacity of the blood by means of Owren's method for quantitative prothrombin-proconvertin determination, which Lund finds well adapted for the purpose. No thromboembolic complications occurred among the patients with coronary thrombosis. Hemorrhagic complications appeared in five cases, wholly or partly due to the reduction of the prothrombin-proconvertin content of the blood by the bishydroxycoumarin; two of these patients died. There were eight fatal cases in all: four with myocardial infarction, including the case complicated with pericardial hemorrhage, one case of coronary sclerosis and one of aspiration pneumonia, the second fatal case with hemorrhagic complications, and two cases with thromboembolic complications after withdrawal of the bishydroxycoumarin therapy.

Long-Term Bishydroxycoumarin Therapy of Coronary Thrombosis and Other Thromboembolic Disorders.—Sixteen of the patients with acute coronary thrombosis reported on in Lund's preceding article were treated on an ambulant basis with bishydroxycoumarin (Dicumarol) for from 2 to 17 months after discharge. No further thrombosis or thromboembolic complications occurred during the treatment. One patient died after treatment ended. Two of three patients with thrombophlebitis in the lower extremities were free from symptoms during bishydroxycoumarin treatment for from 2 to 11 months; the third patient had three recurrences of his thrombophlebitis during the eight months' continuous treatment. In 4 of the 19 cases there were major hemorrhagic complications, none of which were fatal. Lund concludes that ambulant bishydroxycoumarin treatment of thromboembolic diseases for months is possible when patients are kept under close control, with employment of a reliable method for determination of the prothrombin-proconvertin content of the blood, but application of the treatment in the general practice is not advised. The patients must adhere to the prescribed dose of bishydroxycoumarin and must be informed of the danger of spontaneous or traumatic hemorrhage. Even if these conditions are fulfilled, a certain danger of grave hemorrhage is present.

Prophylaxis and Morbidity of Rickets. T. F. Hellbrügge and R. Hatz.—p. 577.
*Toxoplasmic Encephalitis. K. Weisse and W. Krücke.—p. 597.
Problem of Etiological Significance of Certain Serologic Coli Types in Enteritis of Infants; Communication II. P. Krepler and W. Zischka.—p. 625.
Chemical Determination of Vitamin D in Milk Subjected to Ultraviolet Irradiation. O. Hövels.—p. 646.

Toxoplasma Encephalitis.—The authors report on Toxoplasma encephalitis in a 53-year-old woman and in six children. The woman had a sudden attack of vertigo, vomiting, spastic paresis of the right arm, and increasing stupor; symptoms of a brain tumor were present at the time of death. Postmortem microscopic studies revealed disseminated encephalitis with extensive small and large granulomas of the medulla and the cortex, with predilection for the subcortical medulla. There were extensive recent necroses without a granulation wall, but with a high degree of inflammatory edema, particularly of the medulla. In the marginal zones of the necroses there were numerous isolated Toxoplasma organisms and occasional pseudocysts. There were numerous isolated parasites in the small granulomas. A 9-week-old infant presented the pathological picture of hemorrhagic, necrotizing encephalitis with calcifications and numerous isolated Toxoplasma organisms and occasional pseudocysts. A 4-week-old infant died of progressive dystrophy; no clinical diagnosis had been made and a cerebral process had not been suspected. The pathological picture was that of a necrotizing encephalomyelitis with numerous necroses in the deep layers of the medulla and considerable pseudocalcifications on the margins. Only occasional intracellular parasites were observed. In the other four children a severe internal hydrocephalus resulted from the intrauterine-acquired Toxoplasma encephalitis, and in one living patient the parasites were demonstrated in the cerebrospinal fluid on culture and in the peritoneal exudate of white mice. In six of the seven patients diagnosis of Toxoplasma encephalitis was established by the demonstration of the parasites. The case of the adult patient with its eight week course and its pathological picture does not correspond to previously reported observations on Toxoplasma encephalitis. The occurrence of Toxoplasma encephalitis does not depend on age; the congenital types occupy a unique position, although they need not differ from the acquired type of the disease in histopathological changes and localization. The following classification, independent of the age of the patient, is suggested: (1) the meningoencephalitis form with ependymitis and frequently with internal hydrocephalus; (2) the metastatic, focal encephalitis, and (3) the large Toxoplasma granuloma, as in the authors' adult patient. Three characteristic phases of the morphological picture may be distinguished: (1) serous or hemorrhagic exudation through damage to the vascular wall of the arteries and the veins, with increased permeability and changes in the wall resulting in occlusion of the lumen through mobilization and proliferation of subendothelial reticular cells, or thrombosis; (2) inflammatory reaction with proliferation of mesenchymal and ectodermal supporting tissue, necrosis and secondary organization with or without participation of inflammatory cells; (3) repair with cicatrization, formation of cysts and calcification. Diagnosis can be established only by the demonstration of the parasites.

Compression Arthrodesis of Knee Joint.—Compression osteosynthesis by means of a double wire and tightening lever, which was developed for the treatment of pseudarthroses in 1945, has proved valuable also in the arthrodesis of large joints. In resections of the knee joint this method proved especially valuable and at the Vienna clinic for the care of accidental injuries this method of compression arthrodesis of the knee joint was used in 15 patients in a period of 18 months. Resection was carried out in such a way that a slice measuring only about 1 cm. was removed from the condyle of the femur and about the same thickness of cartilage and bone was removed from the tibia. The resected surfaces were somewhat oblique so that an angle of from 165 to 170 degrees resulted. This slight bending at the knee facilitates walking with the stiffened joint. Concavity and convexity of the resected surfaces was avoided, because it impaired the stability of the compression arthrodesis. Two Kirschner wires are threaded through the ends of the bones, at a distance of at least 2 cm. from the resected surface and they are then tightened with a lever. The distance of the wires from the resected surface may be as much as 5 cm. For additional fixation a plaster cast is put on, which is split at once. The compression of the bone ends with the double wire and tightening lever is usually maintained for four weeks and then the cast is removed, and a roentgenogram is made, while the wires are still in place. If the resection cleft is adequately bridged and the bones are tightly joined, the wires may be removed and a plaster cast suitable for ambulatory treatment is put on. After another four weeks, the second cast is removed. In 11 of the cases weight bearing could now be permitted, and there was no pain. In two other cases the cast was left to the ninth and tenth weeks. One patient still had pains at the end of eight weeks and so the plaster cast was renewed for another eight weeks. Observations on a case in which 26 weeks were required for bony union of the resected surfaces proved that compression must be instituted immediately after the resection. A technical mistake had been made, in that the tightening lever had not exerted adequate compression and after four weeks no bridging had taken place as yet. Another compression lever was now applied, but the time required for healing was about as long as that usually necessary for healing before the described method was introduced.

Statics of Vertebral Column in Treatment of Tuberculous Spondylitis.—Kaiser comments on various factors that influence the statics of the human vertebral (spinal) column, pointing out that the spine is under continuous tension, which in the dorsal part of the spine is influenced by the thorax. The erect body posture is regulated by tonic reflexes in the region of the neck. For this reason, the position of the head exerts a decisive influence on the statics of the spinal column. This deserves consideration especially in the treatment of tuberculous spondylitis; a corset, which immobilizes the entire vertebral column, is advisable in such cases. The author believes that the spondylitis corset of von Finck is best for patients with tuberculous spondylitis, since it insures fixation of the spinal column in its entire length.

BOOK REVIEWS

A Modern Practice of Obstetrics. By D. M. Stern, M.A., M.B., B.Ch., Obstetrics and Gynæcological Surgeon, West Middlesex Hospital and its annexes, London, and C. W. Burnett, M.D., F.R.C.S., F.R.C.O.G., Obstetric and Gynæcological Surgeon, West Middlesex Hospital and its annexes. Cloth. $7. Pp. 248, with 140 line drawings by Susan M. Robinson. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; Baillière, Tindall and Cox, 7-8 Henrietta Street, Covent Garden, London, W.C.2, 1952.

From their experiences in the delivery of 50,000 patients during the past 16 years, the authors have outlined in an orderly and logical arrangement their practice of obstetrics. The text is illustrated by numerous line drawings and diagrams. The sections of the book are devoted to normal and abnormal pregnancy, normal labor and its complications, the puerperium, operative obstetrics, the newborn baby, radiology, and mortality. The appendix contains a glossary, an etymology of obstetric terms, and sample records. Thus, the student and general practitioner can obtain a complete story of the science and art of obstetrics. Charm is added to this book by appropriate quotations from Shakespeare, which head each chapter and attest the fact that the authors are scholars as well as obstetricians.

The practice of obstetrics in this country and in England varies somewhat, but there is considerable agreement on most major principles. The authors suggest the use of symphysiotomy when the head is low in the pelvis and a narrow outlet obstructs delivery. This operation is of historical interest only in our teaching hospitals. Most patients deliver naturally, and forceps delivery is carried out on strict indications. The use of outlet forceps delivery and episiotomy are common procedures and are used widely in the United States. Placenta previa is classified into four different types, and still another method of designating the degree of previa is introduced. The treatment of postpartum hemorrhage could be expanded, for it is a major cause of morbidity and mortality. The publisher has done a superb job on the format and type of this book. This textbook can be recommended to students and practitioners.

Sacral Nerve-Root Cysts: Another Cause of the Sciatic or Cauda Equina Syndrome. By I. M. Tarlov, M.D., Professor of Neurology and Neurosurgery, New York Medical College, New York City. Cloth. $6.50. Pp. 134, with 65 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Avenue, Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This monograph deals with its subject in a comprehensive manner in 11 chapters, the first 4 of which are devoted to the anatomy of the nerve roots and the filum terminale and their relationship to the meninges. The fifth, sixth, and seventh chapters are concerned with the gross and microscopic pathology and the last four chapters with the clinical aspects. The book is well printed on glossy paper and is illustrated by well-chosen figures. There is a brief but adequate list of references.

The author states that the cysts are relatively common, although he was able to collect only 10 clinical cases from the literature, which included 4 of his own. The cysts arise at the junction of the dorsal root and ganglion, and they may result from hyaline degeneration of the root or ganglion, transudation from thin-walled vessels, or hemorrhage. The cysts produce symptoms similar to those associated with ruptured intervertebral disks by compressing neighboring nerve roots, and they may erode the posterior sacral arch. The diagnosis is made with difficulty, because the cysts do not communicate with the subarachnoid space, usually originate below the end of the thecal sac, and cannot, therefore, be visualized at myelography. The development of slowly progressive changes referable to the sacral or coccygeal part of the cauda equina should lead one to suspect these cysts. Treatment is total excision.

The author states in the preface that negative results of exploration for a suspected ruptured intervertebral disk lead to the proof that perineural cysts are capable of producing symptoms similar to those of a ruptured intervertebral disk. The monograph was written to sharpen the awareness of the existence of these cysts. The author has covered the subject thoroughly; unfortunately, the present state of knowledge is too meager for the reader to obtain any satisfactory information that would help him in making the differential diagnosis between sacral nerve root cysts and other causes of low back pain.

Physiology of Exercise. By Laurence E. Morehouse, Ph.D., Associate Professor of Physical Education, University of Southern California, Los Angeles, and Augustus T. Miller, Jr., Ph.D., M.D., Professor of Physiology, University of North Carolina Medical School, Chapel Hill. Second edition. Cloth. $4.75. Pp. 355, with 49 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

This well-written and easily understandable treatise is written principally for those in the field of physical education. The authors have conducted many interesting experiments, particularly in reference to fatigue. The chapter on fatigue and recovery describes the symptoms of general fatigue, chronic fatigue, the anxiety state, and other interesting notations relative to that subject. The book has 28 chapters, a glossary, tables of weights and measures, and an index. Each chapter has an excellent list of references. This is not a book to be recommended for those in the field of medicine or with advanced training in physiology; however, for those in the field of physical education it is an excellent volume.

Advances in Cancer Research. Volume I. Edited by Jesse P. Greenstein and Alexander Haddow. Cloth. $12. Pp. 590, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1953.

This is the first volume of a projected series of various phases and spheres of cancer research, each article written by an expert in the field. The subject matter of the first volume is directed largely toward animal experimentation, and only three sections are of potential interest to clinicians, namely, those on cytotoxic alkylating agents, nutrition in relation to cancer, and plasma proteins in cancer. The text is replete with bibliography, and there are excellent reviews on electronic configuration and hormonal aspects of carcinogenesis, epidermal carcinogenesis, the milk agents, radioisotopes, and various carcinogenic agents. This book is recommended chiefly for the research worker in experimental cancer.

Prospects in Psychiatric Research. Edited by J. M. Tanner. Proceedings of Oxford Conference of Mental Health Research Fund, March 1952. Cloth. $4.75; 21s. Pp. 197, with 4 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This conference posed for itself the following two problems: "What are the ignorances which today principally hamper our understanding of the nature, prevention, and cure of mental illness? What advances in research are most likely to remove these and so help to reduce the population of mental hospitals and institutions for delinquents?" To answer these questions the conference assembled Britain's leading authorities from nearly every psychiatric field. The contribution of each is of major interest to all those who deal with the fundamentals of behavior.

In an introduction to the symposium, the anatomist Le Gros Clark points out that "intellect" and "emotion" are separable neither psychologically nor anatomically. In microsmatic man only parts of the uncus, olfactory tubercle, and amygdalae

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specificially so stated.

have direct olfactory functions; whereas the so-called rhinencephalon is a complex organ for emotional integration and, via the hypothalamus, controls the bodily expression of affect. The hippocampus, in particular, initiates a well-defined neural circuit through the fornix, mammillary bodies, anterior thalamus, cingulum, and then back to the hippocampus; and yet the functions of this circuit, present in mammals alone and probably mediating "motivational behavior," is unknown. So also, connections from the hypothalamus to the dorsomedial thalamic nucleus and then to the frontal cortex (i. e., those involved in thalamotomy) may be directly concerned with affective experiences; whereas the primitive reticular nuclei of the thalamus may regulate consciousness itself. Similarly, the functions and radiations of the temporal lobe—the most distinguishing feature of the human brain—are for the most part also unexplored. In this respect A. Meyer (page 19) adds, "It would be in keeping with the modern concepts if the functional psychoses turned out in the end to be a problem of the constitution and equilibrium of brain centers rather than disease entities in the Kraepelinian sense."

With regard to recent experimental advances, S. Sherwood reports on "hemicatatonia" in cats after the production of lesions only 1 mm. in diameter located between the mammillary bodies and the red nuclei, and M. Roth Jasper also notes that stimulation of the thalamic interlaminary system produces cortical electroencephalographic spikes and waves accompanied by variations in consciousness. Von Monakow points out that despite the current enthusiasm for cybernetics one must distinguish "servo" (feed-back) theory from functions of information and computing and that these require more specific correlations with cerebral function. Aubrey Lewis, in line with parallel American trends, calls attention to the social background and institutional settings of the psychoses and quotes Morgan to the effect that "wrong hypotheses, rightly worked, have produced more useful results than unguided observations."

In the spirit of interdisciplinary coordination that pervaded the conference, T. M. Wilson agrees with Franz Kallman that "the genetic theory of schizophrenia does not invalidate any psychological theories of a descriptive or analytic nature since schizophrenia can be prevented as well as cured"; nevertheless, according to F. T. C. Slater, 60 to 80% of the unicellular twins of psychotics also become psychotic. V. Bowlby believes that, just as embryonic cells later lose their capacity for versatile adaptation or as Lupus pups older than four months become unable to adopt a new master, so also a child deprived of a favorable environment for the first three years of life becomes unalterably isolated or asocial (i. e., psychopathic) in its patterns of conduct. Armstrong calls attention to the effects of conflict in eliciting "displacement activities" in comparative behavior, such as a stickleback's "irrational" attempt to dig a nest when he can neither fight nor run from an enemy. Such propensities can also be increased by hereditary selection, as in rats bred for eight generations to accentuate over-reactions to stress (C. S. Hall, 1938).

D. Richter contributes an illuminating discussion of cerebral chemistry. M. Reiss calls attention to various significant physiological facts, such as that psychotics excrete steroids every morning at two or three times the normal rate; in chronic mental patients the adrenal cortex is depressed rather than stimulated by corticotropin (ACTH); and arterenol (norepinephrine) found in the hypothalamus and median thalamus has effects similar to lysergic acid, which, in doses of only 30 to 50 mcg., can produce psychotic-like states. G. W. Harris clarifies various neurohormonal relationships by pointing out that the hypothalamus affects the posterior pituitary by neural connections and the anterior pituitary through the portal vessels, thus controlling also the thyroid, the gonads, and other ductless glands; conversely, a lesion in the mammillary bodies, tuber cinereum, or hypothalamus abolishes the corticotropin response to stress.

A. Kennedy, in summing up, states: "The work of Masserman in the United States and the emphasis on the ultimate physical basis of mental processes in Freud's last book, together with a general realization that there is no place for polemics, have given us reason to hope that the period of isolated schools of thought is at an end, apart from the healthy, minor controversies which are an essential stimulus to scientific advance." To which David Henderson adds: "The first thing [psychiatrists need] to do is get the cooperation of our medical colleagues." In fulfillment of the last sentiment, it is difficult to conceive a book of less than 200 pages better organized and written, broader in scope, more firmly packed with trenchant information and stimulating ideas, or more likely to reintegrate psychiatry with the rest of medicine in a joint attack on the problems of so-called mental disorders. The volume is highly recommended to all who are concerned with human behavior.

The National Health Service: A Guide for Practitioners. Edited by Max Sorsby, L.M.S.S.A., Vice-Chairman, Local Medical Committee, London. With foreword by Sir Allen Daley, M.D., F.R.C.P. Cloth. $3. Pp. 267. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; E. & S. Livingstone, Ltd., 16 and 17 Teviot Place, Edinburgh 1, 1953.

This volume is a handbook or manual for practitioners who are in the National Health Service of Great Britain. It explains, in some detail, the organization and operation of the various component committees of the service. It also offers specific information on the rights of general practitioners and patients under the law and provides advice on appropriate action when any of a number of contingencies arise. While useful as a careful elucidation of the organization of the National Health Service and its regulations, the book makes little attempt to be critical or evaluative. Its greatest value, from the American point of view, lies in the outline of the complicated system now imposed on British medicine. The first chapter, a history of the development of social insurance and services, may serve as a warning of the direction in which these steps travel. The activities covered include compulsory health insurance in 1911, unemployment assistance in 1911, old age pensions in 1908, and workmen's compensation in 1880.

The text covers a variety of subjects that may affect the life of the medical practitioners: the statutory bodies such as the Medical Practices Committee, the Local Health Authority, the Hospital Boards; the nonstatutory bodies such as the British Medical Association; and the special services for eye and dental care, maternity services, pharmaceutical services, etc. The last section contains two chapters on the future, and particular attention is given to the deficiencies that need to be remedied. "It has been asserted that since 1948 a service has evolved which benefits only the administrators, doctors, dentists and their immediate ancillary workers. It is certainly true that increased medical benefits are being obtained by the majority of the public at very considerable personal inconvenience" (page 249). These chapters give piecemeal criticisms of specific aspects of the National Health Service. Only lip service is given to an over-all view of the program and to suggestions for definite improvements in the general scheme.

Crime Investigation: Physical Evidence and the Police Laboratory. By Paul L. Kirk, Ph.D. Professor of Biochemistry and Criminalistics, University of California, Berkeley. Cloth. $10. Pp. 784, with 161 illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; 2a Southampton Row, London, W.C.1, 1953.

This book discusses (1) physical evidence in general criminal investigations and (2) laboratory operations and techniques. It is encyclopedic in scope. Designed for the police investigator, the book describes what physical evidence should be collected in the several types of criminal investigation and explains why the discussed evidence has value in apprehending criminals. Laboratory procedures and techniques are explained in general terms, and suggestions are offered concerning the manner in which less technical procedures may be performed when necessary. The book does not sufficiently emphasize the importance of the toxicologist, the pathologist, the serologist, and other medical specialists in criminal investigations and the necessity of cooperation between medicine and law enforcement officials. It may contribute to more nearly complete criminal investigations.

QUERIES AND MINOR NOTES

PERIODIC LOSS OF VOICE

To the Editor:—*A 34-year-old white woman consulted me about periodic loss of voice for the past two years. At times her voice is husky above a whisper. She has no pain, but there is an occasional dull frontal headache. X-ray examination of the chest did not reveal any abnormality, and tuberculin skin reactions were negative. No abnormalities were found on physical examination; bronchoscopic examination was refused. The patient is a waitress and is not able to continue her work owing to her condition. She has had two episodes of coughing up of bright red blood but none for past four months. Her blood pressure was 104/50 mm. Hg. The Kahn reaction was negative. The hemoglobin level was 14 gm. per 100 cc., and the cutaneous (Pirquet) reaction negative. She weighs 158 lb. and has a good appetite. I would appreciate your comment.* *B. Goldberg, M.D., Chicago*

Answer.—The important considerations in this patient are the occasional hoarseness and the hemoptysis. It is assumed that a careful mirror examination of the larynx has been done; if not, certainly it is indicated. The commonest cause of periodic loss of voice is repeated acute infection. Chronic disturbance of the larynx such as that due to inflammatory tumors of the larynx can produce intermittent hoarseness but usually does not. This is also true of any lesion that would produce injury to the recurrent laryngeal nerve. If the hoarseness is due to injury to the recurrent laryngeal nerve, it may be directly related to this patient's hemoptysis. Hemoptysis must be regarded as a warning symptom of importance demanding adequate study. This should include careful fluoroscopic examination of the chest, with particular observation of the dynamics of the respiratory movements and inequalities of ventilation in different parts of the lung. The esophagus should be studied by having the patient swallow a radiopaque capsule and a thick and thin radiopaque mixture in the erect and Trendelenburg positions. Roentgenograms should include a posteroanterior view of the chest in inspiration and expiration, a lateral Bucky (infraroentgen ray) film of the chest, and a lateral view of the neck showing the soft tissue detail. In the event that these show no abnormalities or the significance of abnormal findings is uncertain, direct laryngoscopy and bronchoscopy should be done. Bronchoscopic examination should include direct inspection of the upper lobe bronchi and superior divisions of the lower lobe bronchi by means of a right angle telescope. Secretion should be collected from appropriate areas of the lung and examined for its cellular characteristics, with particular observation for the presence of neoplastic cells. It should also be studied bacteriologically. If these findings are not conclusive, bronchography should be carried out. Since it is usually best to examine each lung separately, two separate sittings are required. If both lungs are studied at the same time, the upper lobe bronchi are usually not properly outlined and there may be confusion as to the location of abnormal shadows. In the event that no evidence of disease is disclosed by the above studies, the patient should be kept under observation and x-ray examinations of the chest repeated at three to four month intervals for at least one year.

ANENCEPHALIC MONSTERS

To the Editor:—*Please give the incidence of the anencephalic type of fetal monsters and the proportion that go to term.* *Robert L. Moore, M.D., Union, Miss.*

Answer.—There are no published figures on the incidence of anencephalic monsters in the general population. In unpublished data from the Chicago Lying-in Hospital, Potter notes that 12 anencephalic monsters were observed in about 15,700 births of white infants, making an incidence of about 0.6 per 1,000 births. Seven were stillborn, and five were liveborn. Two weighed less than 1,000 gm., five weighed from 1,000 to 1,500 gm., and five weighed from 2,500 to 3,000 gm. The rate of growth of malformed infants is often abnormal, but in these cases it seemed safe to assume that five (about 42%) were born at or near term.

LIGHTNING PAINS OF TABES DORSALIS

To the Editor:—*I would like you to recommend treatment for pains due to tabes dorsalis. A patient contracted syphilis in 1926 and within a short time received 10 injections of an arsenical compound. In 1939, he began occasionally to have shooting pains, which became severe in 1944. In 1946, he received 16 injections of a bismuth preparation, and in 1949, he was given penicillin for two weeks. He was hospitalized for hepatitis for 22 days in 1949. In 1950 or 1951, he received 20 to 30 injections of Protamide (a colloidal solution of processed and denatured proteolytic enzyme). In February, 1953, he was treated at a sanatorium for two weeks for vomiting in the absence of abdominal pain. In March, 1953, he was given a successful smallpox vaccination. None of the therapy for syphilis has been effective. The pains last for two to three minutes and come on at irregular intervals. They often awaken the patient at night and at times are severe enough to cause need for a narcotic. The patient claims that only acetylsalicylic acid or whisky gives relief, which is only partial. He is tall and thin, is 45 years old, and appears healthy. He has Argyll Robertson pupils and a blood pressure of 164/100 mm. Hg. The patellar reflexes are absent. Fluoroscopic examination revealed a small fusiform aneurysm of the aorta.* *M.D., California.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—The status of the spinal fluid is an index of what may be accomplished by treating for syphilis a patient who has the severe lightning pains of tabes dorsalis. If the spinal fluid has become negative, either spontaneously or as the result of treatment, the further use of antisyphilitic remedies will not give relief from pain. Antisyphilitic treatment will give relief from pain in about one-third of patients who have an active spinal fluid infection, as indicated by a high cell count. Since the status of the spinal fluid is not mentioned in this inquiry, it is difficult to answer the question. If the spinal fluid is negative, further antisyphilitic treatment is not necessary, even though the results of blood serologic tests are positive. Therapy should consist of avoidance of fatigue, emotional upsets, and exhaustion states and avoidance of "colds" by use of rubbers and long underwear during the winter. Pains may be less severe in a hot dry region than in a cold humid one. Occasionally, removal of foci of infection in the teeth or tonsils or the elimination of infection in a cord bladder, by prostatic resection if necessary, may aid in decreasing the frequency and severity of the pains. During severe attacks of pain, the use of opiates may be necessary, but the danger of creating a habit must be borne in mind. A hot tub bath followed by a drink of whisky and a period in bed wrapped in blankets to induce sweating may help. The liberal use of acetylsalicylic acid and the taking of a hot tub bath are more effective at the beginning of an attack of pain than after the pain has been present for 24 hours or so. In other words, steps should be taken to prevent attacks. The use of vitamin B_{12} has been recommended, and it may have slight benefit in decreasing the frequency and severity of the attacks. The results from surgical procedures such as chordotomy, have been

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

variable; however, the danger of the occurrence of more serious neurological complications as a result of the surgery has tended to minimize the frequency with which this type of procedure is recommended.

Answer.—Lightning pains of tabes dorsalis may persist long after the underlying disease has been adequately treated and is apparently inactive. Bouts of such pain are often precipitated by one of the following trigger mechanisms: 1. A change in the weather, especially a change from fine, mild weather to damp, cold weather, that is accompanied by a falling barometric pressure, may precipitate attacks of pain; many patients volunteer this information, and from most it can be elicited on careful questioning; spending winters in Florida or southern California, when possible, may provide alleviation. 2. Elevation of body temperature, even though one degree or less in amount, such as may be associated with an acute upper respiratory tract infection, almost invariably precipitates a shower of lightning pains. 3. Focal infection, even in the absence of fever, may precipitate pain; it is essential, therefore, that chronic infection in the upper respiratory tract, including the sinuses is eliminated, that abscessed teeth, if present, are removed, and that the frequent tabetic complication of infection in the lower urinary tract is appropriately dealt with. 4. Constipation is another mechanism that tends to bring on attacks of pain, and the patient should be instructed to maintain regular bowel habits, with the use of laxatives if indicated. 5. Fatigue, whether mental or physical, may produce pain, and the patient should be cautioned against it. These widely varying trigger mechanisms for attacks of lightning pains are obviously unrelated on any exogenous basis. They are the same group of mechanisms that tend to make the subjective and objective manifestations of rheumatoid arthritis worse. In view of this similarity, certain patients with lightning pains, especially those who tend to have them daily or several times a week, may be benefited by the prolonged administration of adrenal cortical hormones, especially cortisone for oral use. Fever therapy is often useful in cutting down the incidence and severity of attacks but is contraindicated in the patient described, because of the probable association of cardiovascular syphilis. Further chemotherapy or antibiotic therapy is not likely to be of much help.

PROFOUND EFFECT FROM MORPHINE

To the Editor:—*In treating a patient with congestive heart failure, I mixed 0.5 cc. of morphine sulfate solution (each cubic centimeter containing ½ grain of morphine sulfate with 0.5% chlorobutanol and 0.1% sodium bisulfite) with 2 cc. of meralluride (Mercuhydrin) in the same syringe before injecting the mixture intramuscularly. The patient three hours later had what appeared to be a very profound effect from the morphine. This patient had been given ⅛ grain of morphine before with only the desired effect. Could the mixing of the two solutions have been responsible for this?*

M.D., *New Jersey.*

Answer.—According to the U. S. Pharmacopeia, meralluride injection (Mercuhydrin) has a pH that varies between 7 and 8.5. Therefore, the combination of acidic morphine sulfate with neutral mercuhydrin could result in a precipitation of either one or both of these substances. Since no precipitation was noted at the time of injection, it is assumed that the state of the morphine or mercurial diuretic was not changed by the combination. The patient received 16 mg. of morphine and had previously tolerated 8 mg. If the patient is well over 60 years of age, the use of 16 mg. of morphine could very well have produced the symptoms by the opiate dose alone. These older patients are extremely susceptible to an increase in dosage, and the only previous dose tried had been only half as large. It is, therefore, possible that the patient reacted to the dose of morphine alone, since there is no evidence of interaction of this mercury salt with the morphine and there are no experimental studies indicating possible potentiation by mercurials.

WAS THE PATIENT PREGNANT?

To the Editor:—*A white woman, 37 years of age, has been pregnant four times. The second pregnancy terminated in spontaneous abortion at 16 weeks. During the 16th week of her present pregnancy this woman had a severe enteritis with bloody diarrhea. After this the uterus failed to enlarge and began to decrease in size. Fetal heart sounds were never heard. It is four months since this incident occurred, and there has been no passage of uterine contents. Although the patient is in general good health, she is somewhat depressed by the prolongation of this condition. I would like advice about inducing abortion. Is there danger in allowing this condition to go on indefinitely?*

M.D., *New York.*

Answer.—Much important information was not given. Was the patient actually pregnant, or did she just miss the periods? Was a pregnancy test done? Did the patient bleed from the vagina? Did she have pain or cramps? Is she menstruating now? If she was pregnant, she may have had a missed abortion, in which event the products of gestation may not be expelled until about the date she was due. No harm will be done if the patient is left alone. Hormones are worthless in these cases. If the patient is emotionally upset or if amenorrhea has gone past the expected date of confinement, dilation and curettage may be done. If irregular bleeding occurs, dilation and curettage are more urgently indicated. A pregnancy test would be worth while. The above advice is indicated only if the uterus is getting or has gotten smaller in the last two months.

CONTRAINDICATIONS TO SHOCK TREATMENT

To the Editor:—*What are the contraindications to electric shock treatment?*

M.D., *Illinois.*

Answer.—Each patient for whom electric shock treatment is considered must be evaluated individually, and the advantages to be gained by a possible psychiatric recovery must be weighed against the risks imposed by existing physical disease. Absolute contraindications to convulsive therapy are aneurysm of the aorta, coronary disease, angina pectoris, and tuberculosis in patients with a history of recent hemorrhage or high activity. Recent fractures of bones are important contraindications, and the therapist should consult with a bone specialist to decide how soon after a fracture convulsive treatment can be given. Cerebral aneurysm, brain tumor, and other conditions in which intracranial pressure is increased are absolute contraindications, as are toxic diffuse goiter, acute infections, and thrombophlebitis. Convulsive treatment should be avoided in peptic ulcer and diverticula. Glaucoma and threatening ablation of the retina also are considered absolute contraindications to its use. Among the relative contraindications are generalized arteriosclerosis, fixed hypertension, myocardial disease, tuberculosis, diseases of the joints and bones, organic brain disease, and mild infection of any sort. With respect to these latter diseases, however, Kalinowsky's advice should be followed: "It bears repetition that the seriousness of the physical illness and of the mental condition must always be carefully weighed against each other." Preexisting physical diseases should not be overstressed as contraindicating treatment that, although admittedly drastic, has surprisingly few ill effects on the organism as a whole.

OILY HAIR

To the Editor:—*I would like some information on the proper treatment of very oily hair in white women.*

Warren F. Clark, M.D., Hollywood, Calif.

Answer.—The condition may be controlled and maintained under control but not cured. The treatment consists of the daily application to the scalp of drying agents, formulas for which are contained in all textbooks of dermatology. A popular one consists of salicylic acid, 2 gm.; coal tar solution (liquor carbonis detergens), 8 cc.; camphor water, 45 cc.; and ethyl alcohol (up to 95%), 180 cc.

THYROID CANCER IN TWINS

To the Editor:—*I removed a nodule from the right lobe of the thyroid gland of a 21-year-old woman that proved to be an adenocarcinoma. There is no evidence of residual tumor. Since this patient is an identical twin, is it justifiable to advise that the right lobe of the thyroid gland be removed in her sister?*

M.D., California.

Answer.—Reports in the literature indicate that cancers affect both members of a monozygous twin pair much more frequently than they do both members of a dizygous twin pair. Such tumors are usually of the same type and arise in the same organ in both twins more frequently in monozygous than in dizygous groups. In monozygous twins the age at onset of the tumors is much closer than in the dizygous twins. Although Graves' disease occurs in identical twins, cancer of the thyroid has not been observed in both members of a monozygous pair of twins in a large series of thyroid cancers. Thyroidectomy in the patient's sister would be of no value unless a total thyroidectomy with its risk of parathyroid insufficiency and of recurrent nerve damage were done. In view of the natural history of this type of cancer, careful observation of the sister for a thyroid nodule or for enlarged cervical lymph nodes is advised. Since the administration of certain goitrogenic drugs over long periods of time results in tumors that can be prevented by the coadministration of thyroxin, treatment of any degree of hypothyroidism in this twin with thyroid in maximally tolerated doses is advocated.

LEAD POISONING

To the Editor:—*In the screening of factory workers for possible exposure to lead, is the presence of basophilic stippling of red cells in an otherwise normal blood picture considered pathognomonic of chronic lead poisoning?*

M.D., California.

Answer.—The mere demonstration of qualitative punctate stippling of red cells is insufficient evidence on which to base the diagnosis of lead poisoning. Quantitative enumeration has some merit, and the basophilic aggregation test is still superior. Yet the indication or enumeration of any formed elements of the blood is not pathognomonic of lead poisoning. Such procedures may be of value in the screening of numbers of exposed workmen. Greater reliance may be placed on the quantitative determination of lead in the urine or blood.

RESEARCH ON EPILEPSY

To the Editor:—*Please advise where outstanding work is being done on a cure for epilepsy.* *M.D., New York.*

Answer.—Outstanding work toward the control, if not the cure, of epilepsy is conducted in various medical centers. The interest may vary in each and may be primarily in research or in treatment, the approach may be primarily surgical or medical, and the patients may be primarily adults or children. Centers in New York, Baltimore, Chicago, San Francisco, Montreal, Canada, and Boston are perhaps most active in research. Up-to-date consultative advice and treatment is available in many other cities. If informed of the particular problem involved, Dr. J. K. Merlis, secretary of the Physicians' League Against Epilepsy, National Veterans Epilepsy Center, Boston Veterans Administration Hospital, can give more specific information.

CONDUCTIVE OPERATING ROOM FLOORS

To the Editor:—*I heard a talk on conductive flooring for operating rooms to guard against explosions. Please give any information you have on such flooring that could be installed in an old operating room.*

Paul E. Pearson, M.D., Kansas City, Mo.

Answer.—Of several flooring materials studied by this consultant, two can be recommended on the basis of their performance. One is a conductive, vitreous ceramic tile. The small tiles are ¼ in. thick and require a conductive underbed about 1 in. thick. At present, this flooring is available in black and green tile combinations. To install these tiles the room must be vacated for 7 to 10 days. Additional information may be obtained from the Olean Tile Co., Olean, N. Y. The other flooring material is conductive vinyl plastic tiles measuring 9 in. square and ⅛ in. thick. This is a tough floor covering that is cemented through a copper wire screen to any existing flooring. It is known as conductive Vinylast and is black with mottlings of green and light gray. This material can be installed over a weekend. Additional information may be obtained from Vinyl Products Co., Sheboygan, Wis.

PREGNANCY AND NEPHRITIS

To the Editor:—*A diagnosis of minimal glomerulonephritis was made six years ago in a woman who is now 30 years old. The urine has shown albumin, red blood cells, white blood cells, and hyaline and granular casts on different occasions. Results of phenolsulfonphthalein tests have been good, but there has been evidence of impaired concentration. Daily blood pressure readings during past months have ranged between 130 and 140 mm. Hg systolic and between 75 and 85 mm. Hg diastolic. Previous blood pressure determinations never showed any reading over 120 mm. Hg systolic. The patient is married and is anxious to become pregnant. I have been emphatically opposed to this and would appreciate an opinion.*

Louis V. Jurich, M.D., New York.

Answer.—There is little harm in permitting this patient to become pregnant. She should be given at least one chance. If her condition becomes aggravated, the pregnancy can be terminated. Most likely, she will be able to go through her pregnancy with the production of little, if any, further damaged. Aside from the physical condition involved, the effect on the patient's psyche, not so much now as a few years from now, of not taking at least one chance at having a baby should be considered.

EPIPHORA

To the Editor:—*What causes the eyes to water in the apparent absence of irritation? This condition seems to be associated with nasal involvement in a patient whose lower eyelids are slightly congested.* *M.D., Rhode Island.*

Answer.—Epiphora can be produced either by increased secretion of tears or by obstruction of the drainage system. In the former case, as the question implies, ocular inflammation should be considered and treated. Obstruction of drainage may occur anywhere in the lacrimal passages and may be due to absence, occlusion, or obstruction of any part. A punctum not in contact with the conjunctiva will also prevent drainage. Investigation of the punctum, canaliculus, and nasolacrimal duct is indicated.

DIFFICULTY IN TREATING "SIMPLE ANEMIA"

To the Editor:—*The query regarding difficulty in treating "simple anemia" in* The Journal *(152:1082 [July 11] 1953) reminds me of Dr. Wintrobe's clinical catechism, videlicet, "Before treatment of anemia, a good history must be taken and a physical examination and necessary laboratory work done." As an intern I saw patients who were hospitalized because of "untreatable simple anemia." One patient had hypothyroidism and responded, over a period of time, to replacement therapy with thyroid. Another had azotemia due to chronic pyelonephritis; only the infection could be treated. A third, and more interesting, patient had arthritis and an incidental history of reactions when given transfusions for anemia. This woman also had a skin eruption; her anemia was not due to the arthritis, as previously thought, but to lupus!*

DEVELOPMENT AND FUTURE OF THE SECTION ON NERVOUS AND MENTAL DISEASES

CHAIRMAN'S ADDRESS

Francis M. Forster, M.D., Washington, D. C.

Before considering the formation and the subsequent evolution of the Section on Nervous and Mental Diseases, it is worth while to consider briefly the development of the concept of sections as a whole. When the American Medical Association held its 12th meeting at Louisville, Ky. in 1859, Dr. J. B. Lindsley of Tennessee moved that a committee of three be appointed by the President of the Association to inquire into and report upon the propriety of dividing the Association into sections, "for the purpose of performing such parts of its scientific labor as may relate to the practical branches of medicine and surgery." At this early date in the history of the American Medical Association it was obvious that the scientific programs could be more specifically activated by the division of labor according to the lines of medical interest. The motion of Dr. Lindsley was adopted, and the next day at the meeting Dr. Lindsley recommended that sections be set up on: (1) anatomy and physiology, (2) chemistry and materia medica, (3) practical medicine and obstetrics, and (4) surgery. Later the same day, Dr. H. F. Campbell moved that two sections be added: one on meteorology, medical topography, and epidemic diseases and the other on medical jurisprudence and hygiene. While the Section on Medical Jurisprudence was provided for in the 12th meeting of the Association in 1859, there is no record of its organization until 1865, even though there are references here and there in the minutes of the American Medical Association that papers were referred to this committee. In 1865 the Section on Anatomy and Physiology was abolished and became the Section on Medical Jurisprudence, Physiology, and Hygiene. In 1873 the sections were reorganized and this section became that of medical jurisprudence, chemistry, and psychology. In 1879 the section again was changed and was merged with the Section on State Medicine. In 1883 it was the Section on Medical Jurisprudence, but this was for only a short time and after two years again lapsed. In 1885, Dr. H. S. Campbell, the President of the American Medical Association, recommended in the concluding remarks of his address that consideration be given to the reorganization and the rehabilitation of the Section on Forensic Medicine. By the motion of Dr. Callendar of Tennessee the title was changed to the Section on Medical Jurisprudence and Neurology.

In 1886 the section was again reactivated under the title of Section on Neurology and Medical Jurisprudence. At this time Dr. John P. Gray of Utica, N. Y., was prominent in the resurrection of the section and the combination of psychiatry and neurology was evident in his address, "Psychological Medicine and Nervous Diseases." Dr. Gray died on Nov. 30, 1886, and his activity in this section was therefore short lived. In 1891, the American Medical Association planned for the organization of the National Medical Association under the new constitution and bylaws of this national organization. The eighth of the sections listed was that of medical jurisprudence and neurology. Note that at that time neurology played a role second only to medical jurisprudence; however, in the meeting that same year, this title was reversed and the section became the Section of Neurology and Medical Jurisprudence. Dr. Corothers of Hartford, Conn., was the chairman of the Section in the year 1891, and in his chairman's address he discussed the early psychic symptoms of traumatic brain disease. Thus was emphasized the correlation between the various disciplines that later evolved into this section.

The following year, 1892, the Section of Neurology and Medical Jurisprudence was strongly organized. Dr. Harold M. Moyer of Chicago was chairman and for his address planned to discuss the organization and work of this Section of Neurology and Medical Jurisprudence. However, just prior to the delivery of the chairman's address, the Association, in its general meeting, set forth the policy of each section developing its own executive committee. This autonomy for the Section was apparently Dr. Moyer's goal, and therefore, he did not deliver the prepared paper. Instead he informed the Section of the

Read before the Section on Nervous and Mental Diseases at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

resolution adopted by the Association, and dwelt briefly on the development of the Section. Dr. Moyer himself chose the year 1885 as the point of origin of the Section. In view of the confusing early development of the Section, the opinion of Dr. Moyer regarding the year of origin is particularly valid. Since this date coincides with the first specific reference to our specialties in the title of the Section, it is acceptable and we can consider 1885 as the year of origin of this section. The peculiar liaison between neurology and medical jurisprudence was not particularly happy, and as early as 1897 there were recommendations before the Section to change the name and a tendency toward the elimination of the medical jurisprudence in the title. A historical résumé of the Section was presented by Dr. Hugh Patrick of Chicago on July 28, 1900, in his chairman's address. Dr. Patrick's paper reviewing the section work up to that time succeeded in bringing about the divorce of neurology from medical jurisprudence. He pointed out that the peculiar alliance of neurology and medical jurisprudence was brought about by jealousy among officers of other sections who feared that, if a nervous and mental disease section was set up, much of the good material appearing in their sections would drift into a new section, thus the development of the Section on Medical Jurisprudence and Neurology was a compromise situation. Dr. Patrick pointed out that, of the 444 papers presented before the Section up to that date, only 64 were concerned with jurisprudence; and, of these 64, 39 related to medicolegal relations of nervous and mental affections and therefore rightly belonged before a section on nervous and mental diseases. Dr. Patrick pointed out that the great strength of the Section lies in neurologists and alienists and that medical jurisprudence is only secondary. At this meeting in 1900, the name of the Section was altered to the Section on Nervous and Mental Diseases and has since remained the official title. There was one recent period when an attempt was made to change this to the more modern terminology of Section on Neurology and Psychiatry. This was not felt adequate, because it deleted from the title one group of our colleagues, the neurosurgeons, and also because the present name has a wider appeal and attracts physicians outside our specialties.

This attempted change also pointed out the unique position of our section. There is no other nationwide forum where the three groups of specialists interested in the diseases of the nervous system meet together for their common good as well as for the exposition of their common knowledge before other physicians. The neurologists, neurosurgeons, and psychiatrists have no other national society that includes equally all three groups. This has been true since the development of these fields as separate entities. The Section has always been strongly medical-neurological in its orientation; however, with the evolvement of neurosurgery as a separate discipline, that field came more and more into its own. The greater development of psychiatry after World War I was evidenced by the appearance of an increased number of psychiatry papers on the program.

The autonomy of the Section has been threatened only once. This was in 1916 when the Board of Trustees raised the possibility of absorbing the Section into that of general medicine. This caused a 2 day acrimonious discussion that wove in and out of the scientific session and was apparently sufficiently strong to offset the threat. In 1917 the number of sessions was determined at three per meeting, with a total number of papers of six per session. This has been the pattern ever since. At that time, however, there was some disappointment and annoyance, for the meetings of the session were apparently quite leisurely, carried from 40 to 50 papers, and often extra sessions were held in the evenings to accommodate papers that could not be read during the day. In 1948 there was a possibility of the Section being reduced from three sessions to two per meeting. This possibility was forestalled, however, because of the need to accommodate three specialty groups and because the attendance in the Section had increased, or remained stationary, while attendance in other sections tended to decrease.

FUNCTION OF THE SECTION

We have, up to this time, considered the early formation of sections and the evolution of the Section on Nervous and Mental Diseases; now we turn to some consideration of the role played by this section in medicine. The Section has two main purposes. The first is the dissemination of scientific knowledge, and the second is the judicious use of its influence for the development and maintenance of those fields of medicine with which it is primarily concerned. The most obvious of these two roles is that of dissemination of scientific knowledge; we shall consider that first.

The dissemination of scientific knowledge by the Section is primarily directed toward two groups; first, those that are intimately working in the field of diseases of the nervous system and, secondly, those physicians whose prime interests lie elsewhere. The Section on Nervous and Mental Diseases is not a specialty society. There is adequate representation elsewhere for such societies. There are at least five neurosurgical societies, two major national neurological societies, and the over-all psychiatric society, in addition to the various psychiatric societies representing the various divisions within the total field of psychiatry. It is, therefore, not necessary for the Section to consider itself as taking the place of, or competing with, any of these specialty organizations. It is justifiable to consider the Section as a specialty society only in the sense that it brings together the three specialties as outlined before, and because it serves as the only single forum for all three divisions.

Of far greater importance, from the standpoint of dissemination of scientific data, is the relationship of this section to the physicians in other fields. Our greatest single obligation is to present to specialists in other fields, and even more to the general practitioner, those advances in our own field, the validity of which we stand assured. This, therefore, influences the type of program it is necessary for the Section to propose. It is, of course, important that there be some new and experimental work which will satisfy the interests of the specialists in our field. It is, however, equally important that there be laid before men in other fields, and especially our colleagues in general practices, a background of stable, solid data in our specialties. This material must be proved by time, yet not so much time must have elapsed that the data are readily available elsewhere. This calls for a peculiar balance between the new and the tried, but not hackneyed, remedies and concepts.

In reviewing the topics presented before this section from 1886 up to and including the meeting for 1952, I have been impressed by the timeliness of many of the papers, their durability after the passage of many years, and the paucity of subsequently disproved data. A good example of the timeliness of articles is the presentation in 1913, by Dr. B. W. Sippey, of the validity of colloidal gold solution studies of the cerebrospinal fluid. This was just one year after the original description of the technique. The paucity of subsequently disproved data is indicated by the rarity with which one finds papers such as that on the 1937 program presenting a glowing report on the results of vitamin therapy in muscular dystrophy. The privilege of the secretary of the Section to hold and observe the books of the Section carries with it the intimate opportunity to glance over the development of our field. In 1938, when Dr. Paul Bucy was secretary, he noted three stars in the secretary's book in front of the paper by Dr. Merritt and Dr. Putnam on the use of diphenylhydantoin sodium in epilepsy. The good judgment of Dr. Bucy on the validity and greatness of that paper and the fact that after 15 years diphenylhydantoin sodium is still a mainstay in the treatment of epilepsy are good indications of the durability of the types of papers presented on this program.

Turning now to the second function of our section, we note the Section on Nervous and Mental Diseases and its predecessors have also always maintained a firm interest in the activities of the American Medical Association itself and with various broad policy aspects in the field. We are indebted to the Section for its forthright action in many things. In 1894 the members of the Section were concerned with the problems of institutionalization for alcoholics and recommended that each state construct an asylum for the care of inebriates. In 1918, the Section recommended to the American Medical Association that, in view of the great development of the field of nervous and mental diseases, the American Medical Association undertake to publish a special journal devoted to the field. This resolution was brought before the House of Delegates and gave rise to the publication of the *Archives of Neurology and Psychiatry,* which subsequently became the *A.M.A. Archives of Neurology and Psychiatry.* In 1919, under the leadership of Dr. Patrick, the Section promptly sent a resolution to the Trustees of the American Medical Association thanking them for the organization of the new journal. The promptness with which this section has leaped into action was evident as far back as 1913, when a paper was presented by Dr. C. D. Camp of Ann Arbor, Mich., regarding the presence of seizures and paresis in railroad engineers. The Section immediately went on record as opposing the driving of railway trains by epileptics or paretics and sent this resolution on to the Trustees of the American Medical Association. In 1933, the Section demonstrated concern over the incidence of congenital syphilis and recommended that steps be taken to procure serologic tests in all pregnant women. Not only the general welfare problems have been considered and activated by recommendations sent to the House of Delegates but the Section has been willing to serve in advisory capacities, and thus in 1941 a committee was appointed for one year to aid the committee of the A.M.A. Council on Industrial Health. The work of the foundations and of lay organizations has not gone unheralded. In 1937, on the recommendation of Dr. Hans Reese, a resolution of gratitude was sent to the foundations from the field of psychiatry in appreciation for the interest they had shown in research and mental illness. In 1948, the Section requested that the A.M.A. recognize the Multiple Sclerosis Society for its efforts as a voluntary health organization. While caution must always be exercised by organized medicine in dealing with governmental agencies, the Section in 1946 evinced interest in having the U. S. Public Health Service activate programs in the field of nervous and mental diseases. Of major importance is the role of the Section in the development, in 1931, and the subsequent maintenance of the American Board of Psychiatry and Neurology, Inc. The Section evinced interest in the plan proposed by the National Board of Medical Examiners for specialty examinations in the field of neurology and psychiatry, and in December, 1933, a committee met to form this board. This was under the chairmanship of Dr. Walter Freeman of the A.M.A. Section Committee. The committee from this section played a major role in the formation and early charting of the course of the board. In recent years, the Section has been concerned with the problem of crediting clinical psychologists and the committee of the Section under the chairmanship of Dr. Francis Gerty and later under Dr. Daniel Blain, has dealt with this major problem. The complex ramifications of this have been great, as indicated in the committee reports, and involve not only the clinical conclusions but also legal ones.

CONTRIBUTIONS OF THE THREE SPECIALTIES

We turn now to the role played by each of the three constituent specialties in the development of this section and the role played by the Section in the development of these three specialties. The programs of this section mirror the advancement in these fields. This indicates that the Section and the specialties have served each other well. Neurosurgery is the youngest of the three specialties to have evolved as a separate discipline, and so the appearance of papers primarily neurosurgical was at a later period than in the other two fields. The first appearance of a neurosurgical paper on the program of this section was in 1893, when Dr. John B. Deaver of Philadelphia described the surgical treatment of tic douloureux. The next neurosurgical paper was in 1900, when Dr. H. H. Hoppe of Cincinnati reported on seven patients with brain tumors who had undergone exploration. In 1906 Dr. Allen Starr of New York reviewed the status of neurosurgery. Crucial papers in the neurosurgical field that have appeared on the program before this section are those of: Harvey Cushing, the "father of neurosurgery," in 1922, Dowman and Smith of Atlanta, Ga., on false localizing signs of brain tumors, in 1930, Percival Bailey, on sphenoid ridge meningioma, in 1933, and Speigel and his collaborators, on stereoencephalotomy, in 1951.

The full-fledged development of neurosurgery is evidenced by the turning over of more and more of the time of the Section to neurosurgery, so that since 1948 a just portion of the program, one-third, is devoted to the field of neurosurgery. The quality of the neurosurgery papers has always been excellent, and this portion of the program has become a pillar of strength. The progress of psychiatry is indicated also by the development of the section programs. In the early days of these programs, matters concerning alienists and the problems of medical jurisprudence comprised the bulk of the program. Later, the frank psychoses associated with fever, syphilis, and childbirth became a more and more prominent part of the picture, and gradually the neuroses themselves appeared in the framework of the programs. Interestingly, one of the early papers on neuroses was that of Dr. Weisenberg of Philadelphia, who was primarily a neurologist. The psychoanalytic movement exerted influence continually in this section, although papers of psychoanalytic interest have not been a predominant part of the psychiatric program. The earliest paper dealing with psychoanalytic concepts was that on the subconscious mind by Clark Bell of New York, in 1897. It is interesting that the greatest attendance at the Section in recent years was for the paper by Dr. Leo Bartemeier on the attitude of the physician, in 1950. This in itself is healthy, for it implied that our section not only served in the exposition of the specialty but, from the broad base of psychiatry, could carry before the physician the implications of his obligation.

Various drastic therapy procedures in use in psychiatry have been adequately and frequently reviewed before this section, and thus in 1937 there was a symposium on the prefrontal area with particular reference to prefrontal lobotomy and in 1937 a symposium on insulin shock therapy. In addition to these symposiums, in 1930 Bleckwenn presented before the Section the first data on the use of amobarbital (Amytal) sodium injections in the therapy of psychosis, and the same year Neyman discussed artificial fever therapy for the psychoses. In 1938, Dr. Hans Reese critically evaluated the insulin shock and pentylenetetrazol (Metrazol) shock therapy, and in 1950 the status of transorbital lobotomy was presented and discussed before this section.

Neurology, of course, has always been the mainstay and the center core of the Section. This is by tradition, since it was early known as a Section on Neurology, and, as we have noted before, medical jurisprudence was more or less tagged on by the action of other sections. Neurology has gone through recession and renascence during the years since 1886. The type of program in itself indicates this quite well. The preoccupation with nosologic classification was evident, of course, in the period of the classification era of neurology. One need only go back through the papers of that era and find classic descriptions, for example, Archibald Church's paper on neurology of cervical ribs, which was read in 1919. These earlier programs were primarily on diagnostic neurology, although Charles Mills, when he read a paper on some experience in neurological therapeutics, received no discussion whatsoever of the paper. The sad state of neurological therapy at that time is evidenced by Dr. Mills' concern of the Perkins metallic tractors and the suspension treatment of locomotor ataxia. Dr. Mills sharply observed that neurologists and surgeons were prone, without due consideration of principles, to have recourse to procedures that could not possibly be of any practical service. Among these he included the short circuiting operations on the bowel for epilepsy, craniectomy for imbecility and idiocy, and the nerve stretching procedures for various painful situations. Therapy in neurology has taken an increasingly prominent place in our programs in recent years, so that now approximately one-half of our papers are devoted to therapy. This is, of course, as it should be, for medical neurology has now ceased to be primarily a diagnostic consultative service. The neurologist is no longer wrapped in the glamour of attaching men's names to the patients' symptoms, packing his kit, and walking away from the bed. He is a physician and is interested in therapy, including rehabilitation.

In this modern renascence of neurology, epilepsy plays a prominent role. This is to medical neurology what infectious diseases are to internal medicine. The prominence of epilepsy in the programs of the Section is evident. The first paper dealing with epilepsy appeared in 1891, and, in almost every program since, there has been at least one paper concerned with some aspect of epilepsy. This first paper on epilepsy was by Trowbridge and Mayberry of Danville, Pa., and dealt with status epilepticus. A peculiarly prescient paper in the field of epilepsy was that of Sanger Brown of Chicago in 1895, dealing with disorders of sleep and automatisms in epilepsy. While the treatment of epilepsy has been considered in almost every meeting in recent years, the interest in therapeutics has not been limited to the convulsive field.

In recent years, there have been critical evaluations of the treatment of (1) myasthenia gravis (Dr. N. S. Schlesenger, 1951), (2) Parkinsonism (Dr. R. W. DeJong, 1953), and (3) cerebral vascular accidents (Dr. Clark Millikan, 1952), to mention but a few. The neurological portion of the Section, however, has not become completely preoccupied with therapy, and the alertness of the Section was again shown when in 1936 there appeared a symposium on alpha potentials of the brain. This appearance on the program of papers on electroencephalography so soon after the discoveries of Berger indicates the good judgment of the officers in 1936, for they must have been almost prescient to have realized that this field was definitely here to stay. In 1940, the Montreal group of investigators, guided by Dr. Wilder Penfield, brought before the Section the status of electroencephalography in head injuries, and in 1941 there was an over-all review of electroencephalography by Frederick A. Gibbs. Since that time, electroencephalography has not been treated as such, for it has attained its majority and the threads of electroencephalography are woven into the over-all pattern, as, for example, by Dr. A. Earl Walker on the surgical treatment of epilepsy (1949), and by Dr. William G. Lennox on the hereditary factors in epilepsy as indicated by electroencephalography (1950). This maturation of electroencephalography, fostered by our section, reached its full bloom in the recent International Congress of Electroencephalography and Clinical Neurophysiology in Boston in August, 1953. Before leaving the field of neurology, an interesting note is that the first paper on aphasia before this section was in 1892. The author of that paper is still living and is the venerable centenarian from Cincinnati, Dr. Philip Zenner.

FIELD OF NERVOUS AND MENTAL DISEASES

Putting aside the three disciplines and their treatment as separate entities and turning now instead to the whole field of nervous and mental diseases, the Section has been duly interested in the various aspects of the total system, and history has evoked the interest of other chairmen and authors on the American Medical Association section program. In 1937 Dr. Henry Viets and in 1947 Dr. Stanley Cobb presented historical reviews of the field of neurology. Dr. Throckmorton, in 1941, reviewed the life and works of a former chairman, F. X. Dercum; and Dr. Henry Woltman, in 1934, rendered a historical account of Sir Charles Bell. In 1946, Dr. Percival Bailey, for his chairman's address, presented his critical review of the practice of neurology. Former chairmen have summarized the philosophies of each group, as, for example, Francis Gerty in psychiatry (1949), and Roland McKay in neurology (1945).

The interest in neurophysiology in this section has been strong over the last two decades. In 1934, John Fulton's school of cortical physiology presented a résumé of the physiological benefits in the field of cortical localization, and, in 1938, Larsell and Dow presented their data on the physiology of the cerebellum. The role of electroencephalography in the Section has already been discussed. The chief neuroanatomic contribution in recent years was that of A. R. Vonderahe, who in 1948 succinctly presented the role of anatomy in modern neurology. In the field of neuropathology, the contributions of the late George B. Hassin have been prominent before this section, beginning in a paper with Peter Bassoe in 1919, on epidemic encephalitis, and culminating in his chairmanship paper in 1933, on the circulation of the spinal fluid. The very first paper presenting microscopic pathological data was presented before this section in 1891, on a tumor of the pons, by Dr. L. Hektoen of Chicago.

This section not only has been concerned with its own fields, neurology, neurosurgery, and psychiatry, but has spent considerable time in working on boundaries between our specialties and other fields. In recent years there have been joint sessions, as in 1939, with the Section on Pathology and Physiology. This symposium was devoted to the vitamin deficiencies. In 1940 there was a joint session with opthalmologists, and an important contribution before this was that of Dr. Halstead and Dr. A. E. Walker, pointing out that macular sparing definitely could occur in hemianoptic field defects. In 1942 the problems of poliomyelitis and the problems common to the fields of neurology and orthopedics were discussed in a joint symposium. However, the boundaries between neurology and other fields are covered not only in symposiums but also by invitations to the program and the appearance before the Section of prominent men in other fields. In 1893, Sir William Osler discussed anorexia nervosa. In 1937 Dr. Armstrong presented his monumental data on lymphocytic choriomeningitis, showing that this was definitely a virus disease. In 1944 Dr. Ober presented the orthopedic therapy of poliomyelitis, and in 1946 Dr. Donald Lyle discussed visual field changes in central nervous system lesions. A fruitful liaison between other fields has been found in the realm of discussers; for example, in 1948, Dr. Joseph Stokes discussed a paper on neurosyphilis bringing out the viewpoint of the syphilologist to this particular facet of the field.

The men who have been prominent in this section down through the years present a roster of American neurology. The list is far too long to read. A full list of officers will be attached to the reprints of this paper. The election to the chairmanship is a fairly good assurance of at least one year of life. In the years the Section has met, on only two occasions has the chairman died before the meeting was held. These two chairmen who died in office were Dr. Pierce and Dr. Southard of Boston. A few of the outstanding former chairmen who are no longer living are Charles K. Mills (1892), Hugh T. Patrick (1899), Wharton Sinkler (1906), Morton Prince (1907), T. H. Weisenberg (1908), Dr. M. A. Starr (1909), F. X. Dercum (1915), Bernard Sachs (1917), Peter Bassoe (1922), George B. Hassin (1933), and H. Douglas Singer (1935).

This section of the American Medical Association has always held an attraction for our fellow specialists in other countries. The first foreign guest recorded was R. Burkhardt of Bonn, Germany, in 1891. In 1903 Sir Victor Horsley and Sir William Gowers were elected members of the Section. In 1914, Otfrid Foerster of Breslau and Wilfred Harris of London addressed the Section. In 1921 Richard Rows of London and Pierre Janet of Paris spoke. In 1922, S. A. K. Wilson attended the meeting. In 1945, Th. Alajouanine was the last foreign guest.

In reviewing the activities of this section over the long period of its existence, one cannot help but be proud to be associated with it, nor can one fail to ponder the possibilities of furthering the role of this section. Certainly it has discharged its duty to disseminate knowledge among physicians, and, in addition, when there is some problem that threatens the common good and is in the domain of the field of competence of this section, the members have risen to speak forthrightly and promptly.

FUTURE OF THE SECTION

Looking into the future, there need be no travail. There is no hint that the Section is in jeopardy from within or without. The direction of the Section passes through the hands of its officers in accord with the principle of the rule of the term of office. There is no danger of this becoming a captive organization. There are, however, certain problems, and certain points worthy of discussion. The first of these is the question of membership. There is no fixed membership for the Section, and any physician attending the American Medical Association Annual Meeting can register for the Section. This is quite proper, for no one is barred from attending our meetings. The formation of a fixed membership with encouraged transient membership would have many advantages. One of them might be the more regular attendance by men in these fields at the A.M.A. section meetings. There is not the feeling of belonging that exists in other societies in these fields. Men are often quite willing to come, present their papers, and quietly slip away, and, if they are not on the program, often they do not appear at the meeting at all. Another advantage in a fixed membership would be that, if it were ever felt necessary to set up a budget for the Section, it would be much easier to do so with a fixed membership.

The matter of budget is certainly not pressing. To the best of my knowledge there is only one section, that of ophthalmology, which happens to have a budget of its own and private funds. The chief advantages of this are the setting up of a prize and the publication of the transactions of the Section. The transactions of our section were formerly published but were discontinued in 1919. It does not, however, seem to be necessary at this particular time to publish transactions of the sections. The papers read before the Section are for the most part published in THE JOURNAL and usually quite promptly. Those papers presented here that are too technical for publication in THE JOURNAL appear in the specialty journals, particularly the *A. M. A. Archives of Neurology and Psychiatry*. During the five years of my active association with this section, there has been only one time when the absence of a budget proved to be somewhat of a disadvantage. This was shortly after World War II, when a steering committee was set up composed of the officers of psychiatric societies and the officers of our section had difficulty in attending the meetings or in appointing delegates to fill the offices, since there was no budget to meet this. This, however, proved to be a very minor disadvantage, for somehow the meetings were covered on a voluntary basis, and eventually this steering committee withered. There is no foreseeable similar problem in the future. However, a separate budget would make it easier for the Section to invite distinguished guests.

The scientific programs are ideal for their purposes and one can see no need for any change in the program. Distribution of papers within various fields, the geographic representation on the program, and the high quality of the papers all speak for the success of the Section. We might, however, do more to urge men from other fields to appear at this sounding board. Joint meetings with other sections have not proved particularly satisfactory; not because the meetings themselves have failed but because of the disadvantages that a symposium heaps upon the rest of the program of the Section on Nervous and Mental Diseases. Since we have three groups of physicians with their ancillary groups to accommodate within the specialties, and three days for the meeting, a symposium seriously cramps the functioning of this section.

The three groups became represented each on their own day in the Section in the year 1948. This segregation policy has certain advantages. It is possible for men interested only in neurosurgery, or in medical neurology, or in psychiatry to attend the Section meetings on one day, gather the grist from the mill, and go about other duties. It makes it possible for the judicious arrangement of the meetings to have this one particular group hold its meeting at a time most appropriate and in conjunction with one of the other society meetings. There is, however, a great disadvantage in this procedure, in that there is not the cross fertilization between the disciplines. It is obvious to those who preside over the meetings that the same men are not present from day to day, and particularly is that so of the specialists in these various fields. They attend their own day but do not stay to add their own deliberations and experiences to those of their colleagues. The members of the Section should give some thought to the advantages and disadvantages of this format of the program and convey their feelings to the officer.

There has been a peculiar and interesting trend in the development of the Scientific Sessions of the American Medical Association. The attendance at the scientific meetings of the sections has tended to remain static or to decrease, while the scientific exhibits have become more and more attractive. These improved exhibits are the direct result of the enthusiasm and the labors of Dr. Thomas Hull. Unfortunately, the scientific exhibits are frequently at a distance from the section meetings. From the standpoint of the specialist and of those interested in the growth of the Section, it would be advantageous to have the distribution of the scientific exhibits so they would be in juxtaposition to the appropriate section, for example, the scientific exhibit on the nervous system would be in the foyer of our own section meeting. This, however, would be disadvantageous perhaps for the over-all intent of the entire meeting. Again, this is a point that the members of the Section might wish to consider. Perhaps the name of the Section is somewhat outmoded and the membership might wish to consider modernizing it. I would, however, recommend that if this is done all three disciplines be included in the title, so that it be called the Section on Neurology, Neurosurgery, and Psychiatry. But the present title is superior, for it appeals to the nonspecialists and therefore should be retained.

The future of the Section depends upon the future of the constituent fields and of the American Medical Association. All are virile. Offices are rotated regularly, so there is no threat of capture or stagnation within the frame-work of the Section. The nervous system and its derangements remains a challenge to physicians in all categories, thus the over-all appeal of this section will not diminish in the foreseeable future. Certainly the painful evolution of the Section and the succeeding 68 years of progress in scientific medicine and in leadership augur well. The minor questions I have laid before you for your consideration underline the augury.

Massive Resection of the Liver.—The removal of a large portion of the liver is a relatively infrequent surgical procedure. Few surgeons have had much experience with the operation. Keen reported the first case in the United States in 1892, and in 1899 he removed the entire left hepatic lobe for carcinoma. In reporting this case, Keen included a table of 76 cases of liver resection from the world's literature. Warvi found a total of 570 resected cases of liver tumor to 1945, but in only 223 of the reports was there a complete description of the operations performed with confirmation of the diagnosis by microscopic examination. Tinker found 59 instances of liver resection performed by members of the American Surgical Association to 1939. He concluded that a busy abdominal surgeon at some time would likely encounter one or more hepatic conditions requiring resection. Conditions for which the liver has been resected include hemangioma, primary and metastatic carcinoma, gumma, tuberculoma and trauma. The most frequent indications for liver resection are hemangioma and carcinoma.—Julian K. Quattlebaum, *Annals of Surgery*, June, 1953.

EARLY DEVELOPMENT OF THE PSYCHIATRIST

Bernard H. Hall, M.D., Topeka, Kan.

NOTE.—*The following paper is primarily of interest to medical students and to the younger graduates who are considering advanced studies in the field of psychiatry, many of whom are readers of* THE JOURNAL.—ED.

Psychiatry has been referred to as "the Cinderella of medicine," "the stepchild of medicine," and "the orphan of medicine." Whatever its relationship to medicine may have been in the past, the importance of psychiatry in present-day medical practice is being recognized increasingly, and its usefulness in relieving and preventing human suffering is steadily growing. It has grown rapidly in both its scientific knowledge and its popularity, but many of its aspects remain to be developed. Among the areas not yet fully charted are the problems and processes associated with the education of the psychiatrist. As a member of the faculty of the Menninger School of Psychiatry, where there are approximately 100 young physicians in training for this specialty, I have had many opportunities to observe and participate in the development of a number of psychiatrists. I propose to report from this experience my observations of, and preliminary formulations about, some of the processes involved in the maturation of the psychiatrist.

Psychiatry might be defined as that specialty of medicine that deals with the incongruous. The psychiatrist attempts to alleviate the suffering resulting from disparities between a person's emotional needs and the characteristic ways in which he tries to satisfy those needs. Until the advent of dynamic psychiatry, the incongruous behavior of the mentally ill was usually considered to be inextricably bound to mysticism. Without doubt, the greatest advance in psychiatry within the last 100 years has been the discovery that the riddles of even the most bizarre and abnormal behavior can be understood in terms of the complex functioning of the human organism.

Another incongruity associated with psychiatry is the one between the number of psychiatric patients and the number of trained psychiatric personnel. Personnel are needed at all levels, but here I will consider only the need for psychiatrists. There are about 490 public and private mental hospitals in the United States. These hospitals are overcrowded, with 750,000 mentally ill patients. In fact, over 50% of all hospital beds in the United States are occupied by patients with mental illnesses. The number of Americans who are in need of ambulatory psychiatric treatment can only be guessed at. For these millions of actual and potential psychiatric patients, there are about 8,000 psychiatrists. The latest statistics from the American Medical Association [1] indicate that over one-third of the 1,936 approved residencies in psychiatry are vacant at the present time. Although some 400 young physicians will complete their psychiatric residencies in 1953, an unknown number of psychiatrists will leave practice because of retirement, illness, or death. Almost 1,400 physicians are in psychiatric training at present, but this does not indicate that the incongruity between the number of patients and the number of psychiatrists will change perceptibly in the near future. Mesrop Tarumianz [2] recently estimated that a minimum of 20,000 psychiatrists are needed in the United States to meet the demands of those who recognize the need and importance of psychiatric treatment and psychiatric preventive work.

To study this situation, the American Psychiatric Association held a conference on psychiatric education at Cornell University in June, 1951. The 82 participants included deans of medical schools, leaders in the medical specialties, including psychiatry, and administrators of government agencies and private foundations concerned with medical education. The purpose of this conference was "to promote and preserve the health of the community: by investigating, defining, and helping to develop programs which will improve the teaching of basic and clinical psychiatry; by advancing the medical skills needed to recognize and treat mental illness and emotional maladjustment; by coordinating the efforts of all groups concerned with these problems so that their total resources may be used more effectively." [3]

When the causes of this shortage of psychiatrists are considered, it is noted that the opportunities in the field are multitudinous, yet every area of psychiatric practice, education, and research needs more personnel. There are several factors that inhibit medical students from choosing this specialty. In 1940, Dr. Karl Menninger was asked by one of the chapters of Phi Beta Pi medical fraternity to fill their annual lectureship. The students said that they were particularly eager to have it filled by a psychiatrist, so Dr. Menninger accepted the invitation. After the lecture he stopped at the fraternity chapter house, where, to his surprise, he was asked many questions about psychiatry, the opportunities available in the field, and the opportunities for postgraduate training.

Dr. Menninger was so astonished by the students' apparent interest in psychiatry that he determined to try to learn from other medical students why so few selected it as a career. He visited 12 medical schools in 1944 and talked informally with many medical students. Other members of the Menninger Foundation staff did the same. In 1949, I visited 16 medical schools and used a questionnaire developed by Dr. Menninger, which was devised to sample the attitudes of medical students toward psychiatry. The completed questionnaires documented crucial facts. They revealed the following composite opinion about psychiatry: Psychiatry is vague, ethereal, and mystical; it is divorced from good medicine; it is too subjective; there is a lack of personal gratification in the practice of psychiatry; there is no future in this specialty; the practice of psychiatry requires more ability than other specialties; most psychiatry is practiced in

institutions; psychiatry is irreligious; psychiatry does not help anyone; psychiatry is concerned only with diagnosis and not with treatment. Being psychiatrists, we were eager to discover the origin and development of these expressed attitudes and the way they could be changed.

Before exploring these questions further, I began teaching psychiatric aides.[4] In this situation I had a rare opportunity to observe the attitudes of lay persons toward psychiatry and mentally ill patients. Perhaps even more important, I observed how these attitudes changed and I evolved some hypotheses as to what caused them to change. Along with my colleagues,[5] I soon learned the importance of the basic attitudes toward psychiatry that the new attendant brings with him to the mental hospital. These attitudes seriously affect the quality of the attendant's care of patients. They may also determine whether the attendant remains in the work or seeks other employment. We found that a large part of an educational program for attendants involves providing learning experiences in which he has an opportunity to examine his attitudes and to change them. He is concerned from the outset of his employment with the following questions: 1. Will I get hurt? 2. Will I go crazy too? 3. What is expected of me? 4. Will my efforts make any difference? These personal questions reflect many of the attitudes that are common about psychiatry. The mentally ill patient is often thought of as someone whose behavior is always extraordinary and who, if unleashed, will kill and rape. Mental illness is believed to be contagious, irreversible, incomprehensible, and hopeless. It is doubtful that the new attendant can be taught much about the techniques of psychiatric nursing until he has changed his original attitudes toward mentally ill patients and has found answers to these penetrating and disconcerting questions.

My more recent experiences with psychiatric residents leave me with the unavoidable and uncomfortable conclusion that many physicians arrive for postgraduate training in psychiatry with only a limited knowledge of its fundamentals. I have found the same questions that are asked by new attendants to be foremost in the minds of most residents. Believing that these observations have important implications for psychiatric education, I have attempted to explore their meaning. Even though I have not been able to study the problem with any formal research method, I wish to describe some of the factors that seem to be present in the growth process of the physician who decides to become a psychiatrist. My primitive attempt to study the problem will stimulate others, I hope, to investigate more fully and more scientifically this aspect of medical education.

DIFFERENCES BETWEEN PSYCHIATRIC AND MEDICAL PRACTICE

Traditionally, the young psychiatrist has begun his training in the large mental hospital, caring for psychotic patients. I do not question the validity of this tradition; I wish only to call attention to the fact that it continues and that my formulations are based on observations in a setting where it is in practice. I believe the nature of the physician's initiation into psychiatry, as traditionally practiced, definitely influences his growth as a psychiatrist. It leads him to believe that the clinical practice of psychiatry in a mental hospital with psychotic patients is significantly different from the clinical practice of general medicine and surgery. Much has been done, by improving psychiatric teaching in medical schools, to influence this assumption; the objective of medical educators has been to prove it false. In my experience the assumption still holds true for many residents, and, because of it, such a physician who chooses psychiatry for specialty training has to make significant adaptations as a physician after he enters training in psychiatry.

This assumed difference between psychiatric practice and other medical practice is actually more illusory than real. But because of the resident's relative inexperience with psychiatry as a body of knowledge, with its clinical practice, and with the mental hospital, the difference is starkly real for him. To erase this illusion in medical education, psychiatry must be integrated into general medical education and the medical student must be provided with more meaningful experiences with psychiatric patients. The training in psychiatry in many medical schools is inferior to the training in all other specialties. Perhaps there is an even more basic problem facing the medical educator who wishes to better prepare the medical student in psychiatry. It has been found that many physicians who wish to begin their postgraduate training lack adequate education in the basic sciences of psychiatry—psychology, psychopathology, and sociology. The sciences basic to psychiatry have not yet been considered seriously as sciences basic for all medical practice. All too often, the premedical student has to surreptitiously avoid his premedical adviser if he wishes to enroll in courses in psychology and sociology as well as in the humanities. Because of these many factors, the new psychiatric resident is repeatedly confronted with differences from the medical environment within which he spent his early formative professional life. These differences can be divided into four categories: (1) differences in the patients, (2) differences in the nature of the psychiatric hospital, (3) differences in the treatments used, and (4) differences in the role of the physician.

DIFFERENCES IN THE PATIENTS

In every culture, certain persons are set apart by the group as those who will treat the sick. As the medical student becomes trained, he becomes familiar with a basic pattern in human behavior—when a person experiences pain, he usually goes to another person for relief from that pain. The important role that pain plays in bringing patients to medical attention is commonplace in the physician's experience. The new psychiatric resident soon learns that the role of pain in mental illnesses may be different. The hospital resident in psychiatry may observe that more of his patients are brought to the hospital than seek hospitalization voluntarily and that many of these patients appear to be singularly free of pain. From this he may falsely assume that pain is not a characteristic of mental illness. Through experience, he discovers his mistake and gains respect for the self-curative powers of the human psyche. He finds that abdominal rigidity, elevated temperature, leukocytic response, and involuntary splinting all have their counterparts in psychic illness. The resident comes to realize not only that pain does exist in mental illness but that, judging from the severe reactions to it, it must be the most excruciating of all human suffering. The human organism mobilizes heroic defensive measures to achieve analgesia from psychic suffering.

---

[4] The greatest shortage of psychiatric personnel is in nursing personnel. There are only 11,000 nurses, a fraction of what is needed to care for 750,000 hospitalized, mentally ill patients. Untrained persons are hired to assist with nursing care. These lay workers are called "attendants." There is a tendency now to call them "psychiatric aides," particularly if they have had the benefit of some in-service training.

[5] Hall, B. H., and others: Psychiatric Aide Education, Menninger Clinic Monograph Series, no 9, New York, Grune & Stratton, Inc., 1952.

To the uninitiated, the psychiatric patient's attitude toward his illness may appear to be perverse. Prior to his psychiatric work, the physician may never have known a patient who would not readily admit to his discomfort and to the fact that he was sick. Some psychiatric patients deny that they are sick, avoid stubbornly the implications of their illnesses, and may even attribute the illness to others by saying, "I am not sick; they are the ones that are sick." Such a patient's attitude toward his illness results from factors that, for the patient, are justified; it is not the result of obstinate perversity, as the new resident may think. For some human beings to admit their need for help with personal problems is, for them, equivalent to an attack on their self-integrity, and, as a result, such persons must defend themselves constantly and deny any need for help. The resident finds not only that the psychiatric history deals with the most intimate aspects of a person's life and that the tabooed topics of ordinary conversation become important topics of psychiatric investigation but that for some patients to admit the presence of certain conflicts means that they can no longer deny that the conflicts exist—now it is known to another, so now it is official. Experiences like the one related below soon teach the resident that the patient's expressed attitude toward his illness is not always the same as he subjectively experiences it.

> It was the 17th day of the physician's residency in psychiatry. He reported to his consultant that he had been exasperated by a patient on his ward. The patient constantly demanded time with the physician, only to complain about being held in the hospital against his will. "Lately," the resident added, "the patient has threatened to write his senator and expose this supposed injustice." The consultant asked the resident what he felt like saying to the patient when plied with these demands to be released. The resident answered promptly, "Why, he's too damned sick to leave the hospital." The consultant suggested that the patient would be relieved if he knew that the resident recognized how sick he was. The consultant pointed out that it must be very frightening to feel that one's desperate need for help might not be recognized and that such a patient might try indirectly to determine whether the physician really appreciates his desperate state. The next day the patient again encountered the resident and asked, "When are you going to let me out of this jail?" The resident replied, "When I think you are well enough to leave." The change in the patient's attitude was dramatic. The consultant was credited by the resident with being a man of great wisdom, and the consultant noted in his evaluation of the resident, "Dr. X is beginning to use common sense in his everyday management of psychotic patients. . . ."

The new resident has much to learn about talking with psychiatric patients. Perhaps it is in this area of communication that the resident discovers the greatest difference from his earlier medical experiences. It is not difficult for anyone to describe the pain he experiences during an acute attack of cholecystitis, but it may be difficult to express the frightening experience of a hallucination. The word nervous may mean anything from a slight frustration to the crippling panic associated with feelings of unreality common in the incipient stage of schizophrenia. There are thousands of patients who cannot tell the physician what they feel and what they experience as sickness because they cannot yet trust the physician enough to talk to him about their subjective experiences. My own initiation to talking with a psychotic patient and my reaction to the experience is not uncommon in the early days of being a psychiatrist.

> Having just finished an internship and being impressed with my own ability to size up a medical problem promptly, I asked a new hospital patient to come with me to my office for an interview. After seating ourselves in the office, I began the interview by asking the patient why he was in the hospital. His answer was equally abrupt: "What the hell difference does it make to you?" Not only was this answer unexpected, it temporarily paralyzed me. I entertained fantasies of being beaten by this now classified as "paranoid" patient. But my own defenses served me well, for I concluded that this patient was "too sick to try and talk to," and, as abruptly as I had initiated it, I terminated the interview. Later my supervisor demonstrated what I thought was superior skill with this patient. The patient was not paranoid at all and talked fluently to my supervisor. I noticed, however, that my supervisor behaved differently than I had with the patient. He offered the patient a cigarette and talked about the patient's home town, the fact that that town was known for its high school basketball teams and that the patient had been center on a winning team from that town when he was a senior.' This all appeared interesting to me, but I was impatient with the supervisor. I noted, however, that when he asked the patient, after some 20 minutes of this chitchat, "Well, what brings you here?" the patient freely told the supervisor the story of his recent illness.

Closely associated with the difference that the resident finds in psychiatric patients from medical and surgical patients is the difference in the role of the patient's family in psychiatric care. The patient is a member of a social group and a family, and his sickness develops while he is a member of that group. This fact may lead to certain reactions to the patient's illness on the part of the other members of the family group. For example, the relatives may feel that they have been responsible for the patient's illness and may attempt to assuage their guilt by well-intentioned behavior, which may interfere with the patient's treatment. On the other hand, the relatives may find it necessary to deny the seriousness of the patient's illness and resist accepting the full significance and implications of the illness. They may seek relentlessly what might be called the organic out: "Doctor, are you sure that John does not have a brain tumor?" They recite numerous reports of cases in which persons behaved just like John at another clinic; a brain tumor was found, and after it was removed the person was all right. It is easier to explain the aberrant behavior of a son to the neighbor next door if it can be accounted for on an organic basis. It is no wonder that the term nervous breakdown is prostituted into ambiguity.

Simmel[6] has underscored the resistance that relatives and friends may manifest toward the patient's recovery. If a mother has babied her son all of his life because she is continuously frustrated by an unhappy marriage and needs to feel that another human being is helpless and fully dependent on her, that mother may unwittingly attempt to defeat the purpose of treatment, which is aimed at freeing her son for a life of his own. I recall the letters that one mother wrote to her hospitalized son; they were love letters. It was not surprising when later this same mother found it necessary to take her son from the hospital prematurely and against medical advice. In such situations, the resident may wonder whether the mother should not be the patient; thus, he learns that in psychiatry one may often best treat the patient indirectly by treating the relative of the patient.

DIFFERENCES IN THE HOSPITAL

The sheer size of many psychiatric hospitals presents adjustment problems for the new resident. But the psychiatric hospital is vastly different from the general hospital, where the embryo physician spent his early professional life. The resident soon finds that he must learn new procedures of personal conduct on a closed psychiatric ward. Embarrassed, he may confess to the nurse that he left his ward key somewhere while he was making the rounds. Only then does he fully realize that the key is lost on a ward where there are six patients who are "elopement risks." Deeply chagrined, he helps the nursing personnel begin a systematic search of the ward for the lost key; he avoids their surreptitious, impatient glances at him and interprets them correctly: "When are you ever going to learn?" The physician usually does not learn the tricks of personal conduct on the closed psychiatric ward until after he begins his postgraduate training.

Gradually the resident learns that the psychiatric hospital and its environment is an important therapeutic tool. For example, he learns that maintaining an environment in which a patient cannot commit suicide is the very essence of the treatment of the suicidal patient. He finds that a large part of psychiatric hospital practice lies in the controlled, planned use of the hospital environment. He begins to gain the same medical acumen in prescribing the use of tennis courts, occupational therapy shops, discussion clubs, and room and ward assignments that he previously used in prescribing digitalis for a patient or in maintaining a proper electrolyte balance in a vomiting patient after operation.

DIFFERENCES IN TREATMENT

The physician not only is acquainted with human beings seeking him out for the relief of their pain but is also accustomed to being able, in most instances, to give them some relief. This leads to the difference in treatment that confronts the psychiatric resident. The following report demonstrates how the new resident psychiatrist may respond to the patient's requests for help and how he may misinterpret the significance and meaning of these requests:

> The patient's problem centered around his chronic use of alcohol. He was brought to the hospital by his mother. She was worn out by attempts to control him and also financially exhausted from his alcoholism. The patient presented the resident with a different symptom each time he saw him. There was only one thing slightly irregular about this: the symptoms were all somatic. When the resident called in the consultant, the patient was receiving aspirin three times a day, treatment for dermatophytosis, and sedation at bedtime. A roentgenogram had been ordered because the patient said he thought he had arthritis in his back—"always had pain there." The patient had already been sent to the eye clinic for a re-refraction because he reported that he could not read fine print any more, and a tooth that had lost its filling three years ago suddenly had become painful after the patient was hospitalized. The consultant noted all this and then asked the resident what he thought about these studies and treatments. The resident replied that he did not think any of them were very important, actually, but he did not know what else to do with the patient. The consultant commented that the patient seemed to be receiving treatment for everything but the problem that had brought him to the hospital—his excessive use of alcohol. The resident then volunteered, "But he never says anything about that." In the discussion that followed, the consultant helped the resident to understand that in this instance overattention to the patient's many physical complaints was a way of joining with him in an avoidance of the problem that really needed treatment.

The resident has not been in psychiatry for many weeks before he longs for the specific treatments that he used in medicine and surgery. He recalls that it was easier to calculate, measure, and administer the required cat units of digitalis than he now finds it to calculate, measure, and administer the appropriate amount of passive interest to show toward an assaultive, paranoid patient. He must decide what to do when there is no tumor to extirpate, or drug to measure, for the treatment of the withdrawn schizophrenic patient. Because the concepts of etiology and pathogenesis in psychiatry are far behind similar concepts for most medical and surgical diseases, the rationale in psychiatric treatment is less defined. There are few specific measures at one's disposal for the treatment of the mentally ill.

The physician learns as a part of his medical training to depend on other professional personnel to provide much of the indicated care of the patient. Chances are, however, that he never realized the full extent to which the psychiatrist must learn to work through other personnel. The novice psychiatrist finds that his relationship with the head nurse on the psychiatric ward is of primary importance. His best planned psychiatric treatment can be wasted if he fails to provide the needed supervision for the nurses, psychiatric aides, occupational therapists, and others who may execute this treatment program and whose direct contribution to the patient's treatment may be more obvious than his own. Learning to capitalize on the potential contributions of the social worker and psychologist, who have particular skills to contribute to the care of the patient, is also a part of the psychiatrist's early development.

DIFFERENCES IN THE ROLE OF THE PHYSICIAN

No physician escapes leadership responsibilities. Providing direction and education for personnel as well as for patients is a part of the heritage of the physician; but perhaps the expectation and necessity of a leadership role reaches its height in medicine in the practice of psychiatry. The practice of psychiatry requires, in most instances, the assistance of other professional personnel, and the psychiatrist is called on, particularly in psychiatric hospital practice, to provide the necessary leadership for a team of professional experts. Preparation for this leadership is an essential part of any psychiatric residency training program.

Early in his medical training the physician learns of the importance his remarks and gestures have for the patient. The patients put their lives in his hands, and they listen attentively to his counsel and advice and follow his treatment recommendations, often without question. Every physician knows that his relationship with the patient is his most powerful therapeutic weapon. It often takes some time before the new psychiatric resident appreciates the singular importance of the physician-patient relationship in psychiatric treatment. Many of his early problems are related to his learning how to make the greatest use of his interpersonal relationship with patients. These early problems include many periods of frustration, when he does not know what to do with the psychiatric patient, feels impotent as a physician, and seeks out the "medical" cases on the ward. The psychiatric patients assigned to the new resident receive a superior quality of attention to, and care of, their organic troubles.[7] The resident's order sheets for such patients are characterized by four categories of treatment: (1) laxatives, (2) treatment for epidermophytosis, (3) medicaments for minor upper respiratory tract infections, and (4) analgesics. Precise orders to implement psychiatric treatment are rare in the clinical charts of patients under the care of first year residents.

Without doubt, the most significant cause of the new resident's awkwardness on the psychiatric ward is that he does not know what to do. He is a physician, but none of his patients need the kind of treatment requiring scientific use of the stethoscope, the pharmacopoeia, or the scalpel. To further complicate matters, the patients are usually ambulatory and appear to be in excellent physical condition. This is a tremendous frustration for the newly trained physician; few of his skills, which he has worked so long and hard to acquire, are now of any use to him. Actually, he will need all of those skills acquired in his earlier medical training and experience in the practice of psychiatry, but he needs additional skills, and it is the latter about which he feels incompetent and disturbed.

In psychiatry, the new resident often finds himself alone with the patient with no armamentarium, nothing but himself. Gradually he learns that the scientific use of the self is the very essence of psychiatric treatment. He begins to realize that a smile can be as therapeutic for some as an attenuated typhoid bacillus can be for others, that there are indications and contraindications for body contact with mentally ill patients, and that there are psychiatric risks of life and death, just as there are similar surgical risks. He finds that a lack of insight into his own feelings about a patient can be as deadly as a toxic dose of a drug. He begins to experience the power that exists within him for the treatment of human suffering. He experiences early the power of the physician-patient relationship and begins to realize the importance that he can have in the lives of the mentally ill.

It often takes some time before the resident fully appreciates this importance that he has for the patients in his care. One resident recently learned this forcibly. After having been assigned to a particular ward for several weeks, the resident left for three days to move his family to Topeka. When he returned to the ward he found things to be different. Patients who were ordinarily friendly and cooperative toward him were, after his return, querulous and argumentative, and, in the resident's own words, "they acted like a bunch of sulking kids." The resident began to understand that not only are there techniques of beginning a physician-patient relationship but that there are equally important techniques involved in temporarily interrupting and in terminating a therapeutic relationship. Gradually the young psychiatrist learns that, through the planned, measured use of his own personality, many persons can be freed of the psychic forces that prevent them from enjoying a full and productive life.

COMMENT

This discussion of some of the problems involved in the maturation of the psychiatrist may have had an unsalutary effect on the reader who may be thinking about a future in psychiatry. In conclusion, I would like to emphasize the satisfying rewards that the psychiatrist realizes as he grows professionally. After I left medical school my sense of mastery soon crumbled, and one of the most important things that I learned in my internship was that "it is not all in the books" and "I've still got a lot to learn." Every physician resigns himself early in his professional career to the fact that his medical life is like all life processes—a continuous, dynamic process, and that unless one is willing to allow a kind of personal professional atrophy, one must remain curious, be investigative, and experience daily the pains of professional growth. Few physicians would have it otherwise. No specialty training is devoid of problems for the student.

But what personal reward is there for the psychiatrist who must experience so many problems that are highly colored with very personal meanings? One does not work with psychiatric patients for long, particularly with psychotic patients, before one feels a challenge to learn more about how to relieve mental suffering. One's scientific curiosity is constantly provoked in psychiatric work, and the opportunities for research are unlimited. Like all professions and like all medical specialties, psychiatry suffers from the lack of good teachers. Any who find particular satisfactions in teaching others can easily realize such aspirations in psychiatry. The financial opportunities in psychiatry are attractive. In psychiatry one may work in institutional practice, private practice, medical schools, research, or any combination of these, and realize a substantial income.

But these are not the really basic and cherished satisfactions in the life of any physician. Similar rewards exist in nearly every specialty of medicine, and no other group of men are held in such high regard and with such esteem as are physicians. This is probably true because physicians, as a profession, have been steadily growing as a group of men and women who are known first of all for their humanitarian interest in man. The phrase interpersonal relationship is nowadays used by some as if it had just been coined. Physicians have merited their respect because they have long recognized the importance and objective counsel, as well as treatment for the relief of human relationships and in their relationships with their patients have offered sympathetic understanding of pain.

---

[7] One woman resident was very pleased with herself, when, in her early days at the hospital, she was able to diagnose correctly a case of mumps in one of her psychotic patients. This opportunity to prove herself a competent physician came at a time when she felt particularly incompetent in managing the psychiatric problems of her patients.

Dynamic psychiatry, because of its preoccupation with the treatment of suffering for which there is no organic basis, has likewise become preoccupied with the physician-patient relationship. Perhaps it is in the area of the scientific study of the art of medicine that psychiatry has made and will make its greatest contribution to medical knowledge. For the young physician who wishes to learn scientifically the artful use of his personality, psychiatry, perhaps more than any other specialty of medicine, offers the golden opportunity. The reward offered is that his daily professional work will provide many opportunities for him to grow in stature as a person.

The misunderstood, mentally ill have been mistreated and neglected in the past. These are the patients that the psychiatrists care for every day—those who often are rejected by society, by family, and by friends, The lonely, the sick at heart, the confused, and the despondent are the clientele of the psychiatrist. Included are those whose productivity and potential for happiness have never been realized. The reward that comes to a psychiatrist in personal satisfaction from relieving the tortures of mental suffering is very real, though it is difficult to describe. The psychiatrist must work with the patient for a long time and must, therefore, defer his feelings of satisfaction for a long period; just the same, they are realized. Imagine the pleasure that comes to the psychiatrist who, through a number of years of hard work with a very sick schizophrenic patient, sees that patient slowly freed of his psychic limitations and achieving the maturity that was his biological destiny. Frequently, the patient had been restrained from this by conflicts within him that grew out of his early life experiences that he could not, with all of his natural curative processes, overcome by himself. But with the help of the psychiatrist's continued, prolonged, objective, sympathetic interest and skill, the patient gradually frees himself from a life determined by illness and lives to destine his own fate. This freedom allows him to find a healthy expression for that resourceful, creative, living dynamism known as the human spirit.

PROPHYLAXIS OF ALLERGIC DISEASE IN THE NEWBORN

Jerome Glaser, M.D.
and
Douglas E. Johnstone, M.D., Rochester, N. Y.

Pediatricians and pediatric allergists have often observed that food sensitivities occur much more frequently in the first few months of life than in later infancy, childhood, and adult life. It is assumed that a physiological immunologic immaturity exists in the early months of life that results in sensitization and clinical symptoms caused by absorption from the intestinal tract of unaltered proteins in potentially allergic children. A potentially allergic child is a child who has at least one allergic parent or sibling.[1]

Evidence that infants absorb unaltered protein from the gastrointestinal tract is well established.[2] Actually, as Walzer [3] has indicated, this takes place qualitatively at all ages; quantitative studies have not been made. In the late 1920's Glaser [1] observed frequent intolerance of egg yolk in infants when the food was introduced at the age of three months and rare intolerance when the food was introduced at the age of nine months or later. As a result of this observation it was postulated by analogy that if cow's milk protein, which constitutes the chief source of food and is the commonest cause of food allergy in the early months of life, were completely withheld from the infant's diet until this period of physiological immunologic immaturity passed, the symptoms of milk allergy might be minimized or even prevented.

A previous study [1] demonstrated the practicality of feeding infants from birth on a diet in which a soybean milk formula (Mull-Soy) completely replaced cow's milk. It was possible to feed successfully all but less than 15% of newborn infants on such a substitute for human milk or cow's milk.

The purpose of this study was to determine whether completely withholding cow's milk from the diet of potentially allergic newborn infants through the early months of life would influence the development and magnitude of major and minor allergic diseases not only during that period but also after the addition of cow's milk to the diet at a later age. The difference between major and minor allergy is largely one of degree. We consider the presence of any asthma as evidence of a major allergy, but a small area of atopic dermatitis (eczema) that responds promptly to treatment or a transient urticaria or a gastrointestinal reaction to an unimportant specific food like squash, for example, is considered a minor allergy. Minor allergies in this study did not present problems of any significance and, therefore, are not considered in detail.

METHODS

The experimental group of 96 infants were all either offspring or siblings of one or more persons with one or more allergic diseases, i. e., asthma, atopic dermatitis (eczema), pollinosis (rose or hay fever), and perennial allergic rhinitis. Cow's milk was withheld from each infant from the day of birth. Eighty-eight were given soy-

bean milk; three were exclusively breast fed; and five were given meat base formulas.[4] In order to minimize the chances of sensitizing an infant through breast milk, eggs, foods consisting largely of eggs, and all cheeses were omitted from the mother's diet; the cow's milk intake was limited to a pint a day boiled 10 minutes, and a variety of the permitted foods was recommended. A sufficient intake of calcium and phosphorus was assured by suitable medication. When the mother could not or would not nurse or the breast milk failed, the child was given soybean milk. The starting formula usually consisted of one-third soybean milk and two-thirds water and was increased to equal parts of soybean milk and water as the infant became accustomed to it.

The ages at which cow's milk was introduced into the diets of the infants were: under one month (5), one to three months (19), three to six months (17), six to nine months (50), and over nine months (5). Their allergic histories were reviewed up to the time of this writing for the incidence of allergic disorders previous to and after the introduction cow's milk into the diet. The follow-up periods were 7 to 12 months (15), 1 to 2 years (14), 2 to 5 years (45), and 5 to 10 years (22).

The histories of 70 siblings of infants in the experimental group were reviewed for the same data, as a control group. Only 65 were included in the control group, since the other 5 could not be followed as long as their counterparts in the experimental group. It was recognized, however, that such an experimental group might have a greater incidence of allergies than would occur by chance in a random sampling of potentially allergic children, since many of the infants were placed on the experimental regimen because their siblings had atopic dermatitis, asthma, or some other major allergy. Consequently a second control group of 175 subjects was chosen from the histories of 4,710 children in 1,215 allergic families. These children were followed for the same number of years as their counterparts in the experimental group and had the same number of younger siblings with similar allergic histories. Their parents also had allergic histories closely resembling those of the parents of children in the experimental group. Members of the sibling and the nonrelated control groups were considered to have allergic disease only if their symptoms had occurred by or before the age of their counterparts in the experimental group.

RESULTS

The incidence of major allergy in the three groups is shown in the table. As far as they have been followed, 14 (15%) of the experimental group have shown major allergic diseases as compared with 42 (64%) of the sibling control group and 91 (52%) of the nonrelated control group followed to comparable ages. Thus approximately four times as many infants in each of the two control groups had major allergic diseases as in the experimental group. The probability that this difference is due to chance is less than one in a hundred (chi square = 16, $P <$ than 0.01). The differences among the groups in the incidence of atopic dermatitis and the incidence of major allergic diseases subsequent to atopic dermatitis are significant (chi square = 19 and P is < 0.01 for the incidence of atopic dermatitis and chi square = 6 and P is < 0.01 for the incidence of sequelae to atopic dermatitis). The incidence of milk allergy and the subsequent occurrence of major allergic diseases in these infants are likewise statistically significant (chi square = 20 and P is < 0.01).[*]

One very interesting family in this survey consisted of five children, all of whom were allergic to cow's milk at birth. In two of these, cow's milk caused atopic dermatitis and in two others, both atopic dermatitis and asthma. By contrast, the fifth sibling, who was given soybean milk from birth, has not had any major allergies by 6 years of age, despite the fact that he had diarrhea from cow's milk at 8 months and still cannot tolerate it.

COMMENT

Perhaps the greatest significance of these findings is the possibility of applying the general principles of prophylaxis to the immunologic and allergic management of potentially allergic children. Pediatricians have been concerned with the physical and mental growth and development of infants, with emphasis on prevention of infections and nutritional, orthopedic, orthodontic, and psychogenic diseases. Now it may be possible to reduce the incidence of major allergic syndromes, which are such a perplexing part of a pediatrician's responsibilities. Any measure that may reduce the incidence of atopic dermatitis is important in view of MacKinney and Glaser's[5] statement that 80% of infants with atopic dermatitis in infancy have a major respiratory or other allergy by the age of 6 to 10 years.

Incidence of Major Allergy in Children

	No. of Patients	Incidence of Major Allergy	Atopic Dermatitis and Sequelae	Allergy to Cow's Milk and Sequelae
Experimental group	96	14	7 (1 had asthma at 3 years, 6 free of allergy at 6 years)	7 (none at 6 years)
Sibling control group	65	42	21 (15 had major allergies between 4 and 6 years * 6 free of allergy at 6 years)	24 (22 had major allergies at 6 years) †
Nonrelated control group	175	91	50 (30 had major allergies by 5 years,‡ 20 free of allergy at 6 years)	53 (26 had major allergies at 6 years) §

* 10 asthma, 4 pollinosis, and 1 perennial allergic rhinitis.

† 11 asthma, 6 chronic atopic dermatitis, 4 pollinosis, and 1 perennial allergic rhinitis.

‡ 24 asthma and 6 pollinosis.

§ 24 asthma, 1 pollinosis, and 1 pollinosis and perennial allergic rhinitis.

The regimen outlined must be instituted from the moment of birth. To give a potentially allergic newborn infant cow's milk as a trial formula ignores the basic premise of this paper, namely that these children have an immunologic immaturity in the first few months of life that makes them especially predisposed to become sensitized to the first foods introduced into the diet. There is also evidence, although unequivocal proof is lacking,[6] that the fetus may be sensitized to foods ingested by the mother. For this reason, during pregnancy many of the mothers in our experimental group were placed on the special diet previously mentioned for use while nursing to reduce the likelihood of sensitizing their offspring to particular foods, especially eggs and milk. While we have no evidence that this diet actually accomplishes its purpose, we believe that its use is reasonable on theoretical grounds, particularly since it can do no harm. Before any infant was started on the milk-free regimen, the mother was encouraged to attempt a trial of complete breast feeding. This was done because the studies of Grulee and Sanford [7] had clearly shown that the exclusively breast fed infant has seven times as many chances of escaping eczema as the infant fed cow's milk; however, we were unsuccessful in getting any significant number of mothers to do this.

Along with cow's milk, certain other foods such as eggs, beef (closely related chemically and immunologically to cow's mik), and wheat should also be withheld from the diet of a potentially allergic infant until after the period of immunologic immaturity has passed. From Glaser's [1] observations on egg yolk, this period is presumed to vary from between six and nine months. We prefer to feed the potentially allergic infants breast milk, soybean milk, or meat base milk [4] rather than cow's milk and completely withhold the foods mentioned. Sensitization to soybean milk or to the meat base has not yet been unequivocally observed in our experience; however, it may be expected, since such sensitization appears to depend to a certain extent on age and the length of the period during which a food is given. In this event the infant may then be given other meat base milks, or even cow's milk, with presumably less danger of permanent sensitization or sensitization of long duration.

DIFFERENCES IN CALF CIRCUMFERENCE AS DIAGNOSTIC GUIDE TO THROMBOPHLEBITIS

Albert Damon, M.D., Ph.D., New York
and
Ross A. McFarland, Ph.D., Boston

Since thrombophlebitis may provide a source of potentially fatal pulmonary emboli or may herald occult malignant conditions, its early detection can be lifesaving. As White [1] recently emphasized, "We must everlastingly [look to] the leg veins" in pulmonary embolism; the diagnosis can only be decided clinically.[2] It is generally agreed that calf measurement is an important diagnostic procedure. Although mensuration is but one of several criteria for establishing the diagnosis, it occasionally becomes crucial, for example, when the presence or degree of swelling is questionable or leg and chest pain have recently occurred. In the latter, the patient may be afebrile; physical examination shows only a difference between the two calf girths, and laboratory data and chest roentgenogram interpretation are equivocal. The frequency of such cases on the medical service of a general hospital has directed attention to the significance of difference in calf circumference.

In neuromuscular diseases and those of bones or joints, clinical problems that involve bilateral differences in calf girth are also encountered. Bone or joint damage by disease or trauma may result in muscle atrophy detectable only by measurement. In poliomyelitis, arthritis, osteomyelitis, and the muscular atrophies and dystrophies, such measurements can help diagnose current or previous disease, the extent of damage, and the progress of disease or therapy.

The clinician must evaluate measurements in the light of normal differences to be expected between the two calf girths; however, search of the medical and anthropological literature has disclosed no standards for normal adults. In very few studies have both right and left calves been measured, and then by questionable techniques or predominantly on young men, whereas thrombophlebitis occurs most often in persons over 40. The data presented here may help establish standard calf measurements for American men and women; those for thigh girth and for other age and racial groups remain to be investigated.

SUBJECTS AND METHODS

In the course of an investigation of 369 professional bus and truck drivers,[3] both calves were measured to determine the effect of differential use of the legs in driving. Activity analysis of these drivers on several models of vehicles showed that on the average the right foot was in use 99% of the time (81% on the accelerator and 18: on the brakes), whereas the left foot is active but 48% of the time, on the clutch.[4] It was thus assumed that drivers would show a greater calf difference (right minus left) than other groups in the population; but this did not hold true. Indeed, Tanner [5] has shown that calf cir-

cumference may actually *decrease* with severe exercise, as it does during a single contraction.

The 369 drivers were healthy, white men from 20 to 64 years old, averaging 36 years (standard deviation [S. D.]: ±7.8 years), who averaged about 10 years as professional drivers of heavy vehicles. Most of them lived in New York, New England, and Texas, and their national origins were representative of Americans generally. Included in the group were some 100 state champion truck drivers competing in annual nationwide truck "Roadeos." All had excellent current health records. While they were not questioned specifically as to previous vascular or neuromuscular disease affecting the legs, some volunteered this information and were eliminated from the study, as were all with obvious disease.

Maximum horizontal calf circumference was obtained to the nearest millimeter, the subject standing with feet about 12 in. apart and weight evenly distributed on both feet. A metal measuring tape was applied at least three times, at various levels, to determine the maximum contact circumference without pressure. (Values for the completely relaxed muscle, as in patients measured in bed, are about 6 mm. greater.[5])

The same measuring technique was used for a smaller series of 104 healthy, white working women. They were a mixed group (doctors, nurses, technicians, secretaries, students, housewives, and cleaning women), mainly of northwest and central European extraction. Their age ranged from 17 to 68 years and averaged 32.2±S. D. 11.3 years. None had had previous disease affecting the extremities.

RESULTS

The women showed no statistically significant superiority of one calf girth over the other. The left calf was larger by 0.4 mm., with a S. D. of ±5 mm. This sample is probably representative of American women with regard to calf size, at least as judged by comparison with Reynolds and Asakawa's [6] series of 100 middle income, Ohio women averaging 38 years old. (Left calves in the present series and in Reynolds' series averaged 341.8 ± S. D. 24.1 mm. and 347 mm., respectively.) No other series is available for comparison of calf girth difference, so it cannot be stated definitely that women in general have equal calf girths.

The drivers' age, height, weight, and calf girths are shown in table 1 along with those of ROTC cadets and Army flyers, the only other groups so studied. Dunn's [7] ROTC cadets were measured only to the nearest 5 mm., whereas Elbel's [8] data on flyers are not presented in a form permitting statistical analysis of the calf girth difference. The average difference can be approximated (by subtracting left from right mean calf girth); the standard error of this average cannot be computed. The significance of the difference between the drivers' mean value and the pilots' is thus uncertain; the drivers and the ROTC cadets do not differ significantly. Single calf girths of several other series of men measured by a similar technique [9] are included for comparison.

Two points emerge from table 1: (1) drivers were comparable in calf circumference to other groups in the population, with regard to average circumference and bilateral difference; age and occupational habits seemed to affect calf girth little, if at all; and (2) right calf girth consistently and significantly exceeded the left in the series of men studied. Calf circumference difference, right minus left, in the 369 drivers averaged + 3.2 mm., with a S. D. of ± 6.4 mm. The distribution from which these figures are derived is presented in a clinically useful form in figure 1, which is close enough to the "normal" curve to be regarded as such.

In such a normal distribution, 68% of values lie between the mean ± 1 S. D., 34% falling on either side of the mean. The mean ± 2 S. D. includes 95%; the mean ± 2.5 S. D. includes 99%; and the mean ± 3 S. D. includes 99.7% of the distribution. For calf circumference, a difference, right minus left, of ± 1 S. D., corresponding to – 3 or + 10 mm., may occur by chance one-third of the time and hence can be considered normal. Differences of ± 2 S. D., corresponding to – 10 or + 16 mm., are less likely, with chances that can be read from tables in any statistical text. The procedure is to express the given measurement as distance-from-mean/S. D. For + 15 mm., this is (15–3.2)/6.4=11.8/6.4=1.8 S. D. from the mean, a 3.6% chance that such a difference can occur fortuitously. The usual level of significance is arbitrarily set at 1 to 3% (chances 99:1 to 33:1 against a normal occurrence of the given measurement). For practical purposes, the clinician may use ±2, 2.5, or 3 S. D. Corresponding to these limits, beyond – 10 or + 16 mm., only 5 in 100; beyond – 13 or + 19 mm., only 1 in 100; and beyond – 16 or + 22 mm., only 0.3 cases in 100 will occur in normal men. Whatever level of significance the clinician accepts, he will of course consider calf girth difference as only one diagnostic criterion.

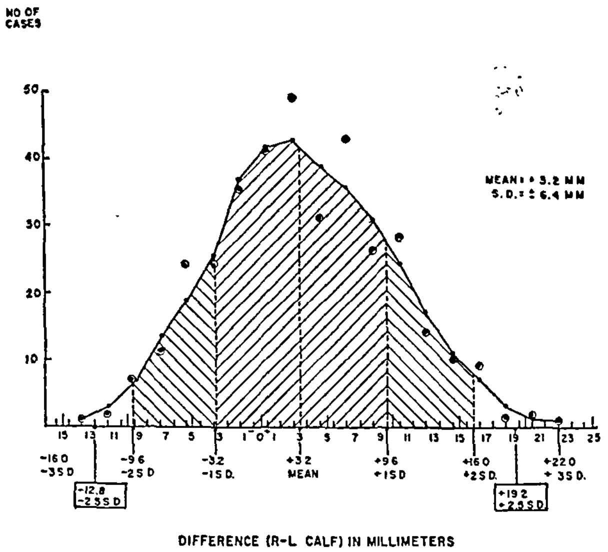
OTHER OBSERVATIONS

There is a marked difference among various persons in ability to discern slight inequalities in calf circumference. In this series experienced physical anthropologists could not always decide this by inspection alone when differences ranged between 10 and 15 mm. It seems reasonable, therefore, that measurement should be routine. Among the men, the average of the two calf girths is unrelated to age (coefficient of correlation [r] = –0.03). Calf girth difference is also unrelated to age (r = + 0.04). Average calf girth and calf girth difference are themselves independent (r = + 0.06). Handedness cannot be used to "explain" the superiority of right over left calf girth or to predict which calf will be larger, since the coefficient of correlation (r) between calf girth difference and the dextrality index (left hand grip as a percentage of right, as measured by a Collins dynamometer) is –0.09. (All r's have a standard error of ±0.05). This may be stated in another way. Excluding the 210 "mid-range" subjects with calf girth difference less than ±2 mm. or a dextrality index of 95 to 104%, or both, of 132 strongly right-handed drivers, 31% had larger left calves, and of 27 strongly left-handed drivers, 68% showed larger right calves.



Distribution of calf circumference difference, right — left, in 369 healthy men (bus and truck drivers).

CLINICAL APPLICATION

To test the theoretical expectations, calf girth differences were noted in 109 consecutive patients at Presbyterian Hospital who had acute thrombophlebitis of the leg veins. The measurements were made from 1949 through 1952 by many observers and by many techniques, but they were always made always at corresponding levels for the two calves. Mere notation of apparent presence or absence of swelling outnumbered actual measurement by about 10 to 1, possible evidence that measurements were made chiefly in doubtful cases. Similar values were found among Negro and white persons on whom exact measurements were made (7 Negro and 54 white men and 7 Negro and 41 white women). No cases were found in which the larger calf was the unaffected one, nor were any included in which disease other than thrombophlebitis affected the legs. The expected increase in calf girth inequality between normal and thrombophlebitic subjects is shown in table 2.

However, these averages reveal nothing about the borderline cases, which pose the diagnostic problem. A "cut-off" point (the upper limit of normal) is desirable for excluding normal persons and detecting cases of thrombophlebitis. As shown in table 3, the most practical figures are ±15 mm. for men and ±12 mm. for women. Less than 4% of normal men exceed ±15 mm., whereas 80% of thrombophlebitic patients do. (The use of 2.5 S. D., beyond —10 and +16 mm., is even better, including only 1% of normal persons and detecting 84% of thrombophlebitic patients, but 15 mm. is easier to remember). Only 1 to 2% of normal women's calf differences exceed ±12 mm., while 77% of the thrombophlebitic women's do.

TABLE 2.—*Calf Girth Differences in Health and in Acute Thrombophlebitis**

(Right — Left Calf, in Mm.)

	Normal Persons			Thrombophlebitic Patients		
Men	No.	Mean	S.D.	No.	Mean	S.D.
R > L	230	+6.7	4.6	30	+30.5	15.7
L > R	104	—4.4	2.8	31	—28.6	9.7
Women						
R > L	50	+4.9	3.5	23	+31.1	21.2
L > R	38	—4.9	2.8	22	—25.9	15.0

* Data on 35 normal men, 16 normal women, and 3 thrombophlebitic women with equal calf girths are omitted from table.

No such arbitrary figure can make the diagnosis automatically; it is merely a guide to be used in conjunction with other diagnostic criteria. As always, the clinician makes his final judgment on the basis of all the evidence.

SUMMARY AND CONCLUSIONS

Bilateral differences in calf circumference of 369 healthy, white men (bus and truck drivers) are presented in the figure as a guide in the diagnosis of thrombophlebitis and possibly in the diagnosis and management of neuromuscular and bone or joint disease. The men, whose ages ranged from 20 to 64 years and averaged 36 years, had an average calf girth difference of 3.2 mm., right exceeding left, with a standard deviation (S. D.) of ±6.4 mm., confirming previous reports on younger men. Similar measurements for 104 healthy white women averaging 32.2 years old and without previous disease of the extremities, show no difference between the calves.

TABLE 3.—*Calf Girth Differences in Acute Thrombophlebitis: Percentages Exceeding Indicated Differences*

(Right — Left Calf, Mm.)

	No.	±2 S.D.*	±2.5 S.D.*	±3 S.D.*	±12	±15
Men	61	—10	—13	—16	....	....
		+16	+19	+22	....	....
		84%	84%	75%	....	80%
Women	48	±10	±12.5	±15	....	....
		77%	75%	65%	77%	....

* Standard deviation based on 369 normal men and 104 normal women.

Based on 109 consecutive cases of acute thrombophlebitis, as well as on normal distributions, the most practical upper limit of normal calf girth difference appears to be ±15 mm. in men and ±12 mm. in women. Calf girth difference in about 4% of normal men and 80% of thrombophlebitic men exceeds ± 15 mm. In about 1 to 2% of normal women and 77% of thrombophlebitic women it exceeds ± 12 mm. Negroes with thrombophlebitis show calf girth differences comparable to those of white patients, so the figures apply to both races. In normal men, there is no correlation between age and calf circumference, age and calf girth difference, average calf girth and calf girth difference, or right or left calf girth superiority and handedness.

Variable individual ability to discern calf inequality and the difficulty of trained anthropologists in estimating 10 to 15 mm. differences in calf size make routine measurement desirable in suspected thromboembolic, neuromuscular, and bone or joint disease.

ASYMPTOMATIC FRACTURES IN OSTEOPOROTIC SPINES OF THE AGED

J. Gershon-Cohen, M.D., A. M. Rechtman, M.D., Harold Schraer, Ph.D.
and
Nathan Blumberg, M.D., Philadelphia

Asymptomatic vertebral fractures in osteoporotic spines of the aged stand out in sharp contrast to the urgency and seriousness of acutely traumatized spines in younger persons. The peculiarities of these fractures form the basis of this report. In the Home for the Jewish Aged, in Philadelphia, 136 residents were selected for study because they were ambulatory and in good health. Their ages ranged from 63 to 95 years. Anteroposterior and lateral x-ray examinations of the spine were made as part of the clinical survey in each case.

RESULTS

Fractures were found in 35 (25.7%) of the 136 cases, in 11 (20%) of the 54 men and in 24 (29%) of the 82 women (table 1). Single fractures in the dorsal spine alone occurred in 14 cases and in the lumbar spine in 7 cases. When multiple fractures were present, they were confined to the dorsal spine, in 6 cases, or in the combined dorsolumbar area, in 9 cases; multiple fractures always were found in association with one or more fractures in the dorsal spine. The 12th dorsal and the first lumbar vertebrae were most frequently fractured. Only one or two fractures were found in most spines, but there were as high as seven fractures in one case (table 2).

All spines revealing fractures were osteoporotic, but, unfortunately, the intensity could not be determined, since no satisfactory measure of osteoporosis has yet been devised.[1] The deossification of the spine, in many cases, was associated with codfish deformities of the vertebral bodies. Contractures, narrowing, and contour irregularities of the intervertebral spaces adjoining the fractures were noted uniformly, but otherwise these spaces usually were widened and sometimes were almost spherical. Hypertrophic osteoarthrosis or degenerative changes were found in all spines of this group. Seldom were these changes generalized, and in the patients with fractures, the hypertrophic irregularities were most marked in the area of fracture. Kyphosis of the upper dorsal spine was common to the whole group. Rarely was kyphosis or scoliosis localized to the fractured site.

Most fractures involved the upper anterior portion of the vertebral body (fig. 1). Occasionally, the entire upper surface of a body showed evidence of collapse with herniation of the nucleus pulposus into the crushed area,

1. Gershon-Cohen, J.; Schraer, H.; Sklaroff, D. M., and Blumberg, N.: Dissolution of Intervertebral Disc in the Aged Normal: The Phantom Nucleus Pulposus, Radiology, to be published.

(fig. 2). The close resemblance of these fractures and the secondary changes of healing to those fractures following an acute injury was remarkable. The case shown in figure 3 fortuitously furnished evidence of all phases of fracture without symptoms in the aged. The fracture when first seen in this 81-year-old woman was recent and resembled that which might have occurred after acute trauma in a younger person (fig. 3); yet she did not give a history of recent injury, and she had no complaints. No restriction was noted in her activities, which comprised keeping her room tidy and moving about freely. Too impatient to wait for an elevator, she walked up and down one flight of stairs at least three times daily for her meals. Because the fracture of the first lumbar vertebra obviously was recent, even though she gave no history of injury, this patient was watched with the expectation that, sooner or later, she would complain of back pains and require orthopedic attention. Nothing like this occurred. She had no complaints, and repeated x-ray examinations (fig. 4) showed complete healing without deformity or disalignment, in spite of the fact that no treatment was given.

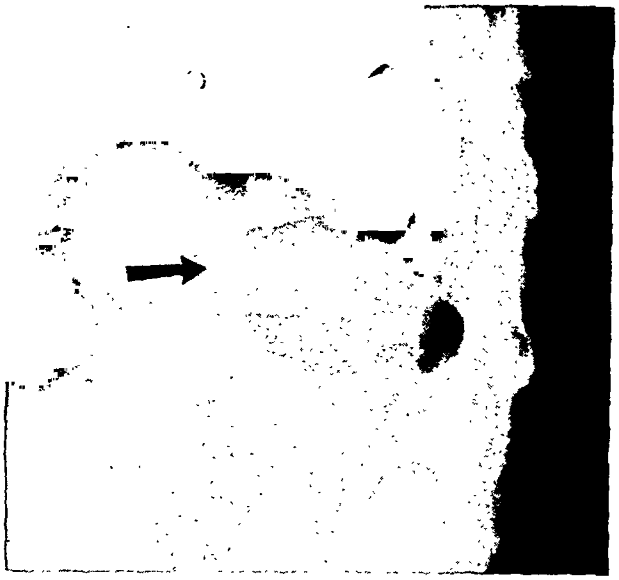

Fig. 1.—Asymptomatic healed fracture of upper anterior portion of the body of the 12th dorsal vertebra in a man 76 years old.

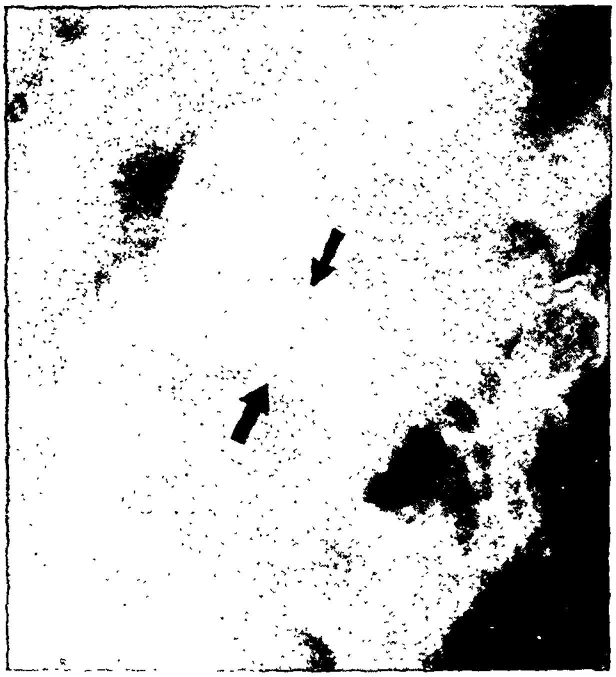

Fig. 2.—Asymptomatic healed fracture with disruption of the proximal nucleus pulposus, which has herniated into the body of the 2nd lumbar vertebra in a 73-year-old man.

Not a single history of fracture was elicited in this group, and, therefore, not a single patient was treated for fracture. Even more remarkable was the absence of any clinical findings indicating disability. Persons with fractured vertebrae could not be distinguished from those without fractures, just as was observed in six similar cases by Nathanson and Lewitan.[2]

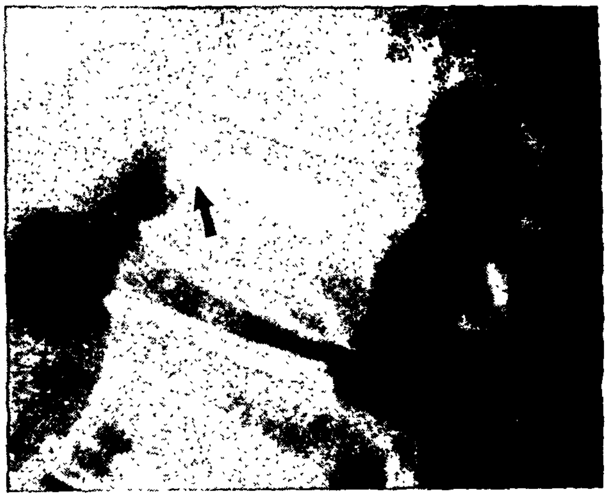

Fig. 3.—A recent asymptomatic fracture through the upper anterior portion of the 1st lumbar vertebra in an 81-year-old woman.

COMMENT

In older persons, retardation of osteoblastic activity is involved, rather than bone absorption. Aggravating factors may be present, such as a decreased blood supply due to arteriosclerosis, evidence of which was prominent in the collateral x-ray studies of the aorta and large vessels in this series of cases. Steindler suggests an increased frequency of focal aseptic necrosis resulting from a precarious blood supply as an explanation for the ease of traumatism in the bones of the aged.[3] Among other causes for senile atrophy, he mentions defective alimentation and inanition, with loss of calcium and phosphorus. Since these substances are still excreted in the urine, the loss is covered at the expense of the skeletal system. Other factors to be considered in the aged are the higher incidence of deficient gastric hydrochloric acid and hepatic and pancreatic secretions. Such factors lead to inadequate absorption and utilization of ingested calcium, fats, and vitamins A and D. Finally, hypofunction of the endocrine system must be considered, particularly of the pituitary, thyroid, parathyroids, and gonads. It is no wonder that a simple panacea has not been discovered for the prevention or cure of senescent deossification.

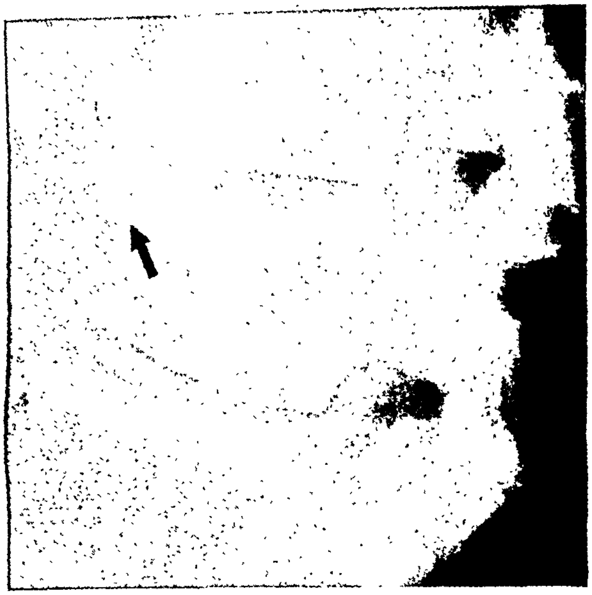

Fig. 4.—The fracture shown in figure 3 after it had healed. There were no symptoms, and no. therapy was given.

Since the bones of the aged are brittle and fragile, they are susceptible to fracture. The spinal column particularly shares in this process under the continuous influence of body weight. That fractures should occur without producing symptoms, as in younger persons, comes as a surprise. The medicolegal implications that may arise under such circumstances can be misleading and expensive. Solid healing of these fractures without special treatment evidently occurs, because the anatomic defect of the fractured vertebra, even though marked sometimes, does not interfere with the stability of the spine. A similar conclusion in a study of fractures among miners was reached by Nicoll.[4] Also, already established is the efficiency of conservative treatment of spinal fractures in the aged.[5]

SUMMARY

Among 136 healthy residents of a home for the Jewish aged in Philadelphia, one or more asymptomatic fractures of vertebrae were found in 35 (26%). The 12th dorsal and the first lumbar segments were most frequently involved. Osteoporosis, with degenerative changes, occurred in most cases, but no unusual disalignment was present at the level of the fractures. Moreover, detailed clinical examinations revealed no objective evidence of these untreated fractures, in spite of their close resemblance to those occurring after acute trauma in the younger person.

A FIVE YEAR STUDY OF TUBERCULOUS CHILDREN TREATED WITH STREPTOMYCIN

CHAIRMAN'S ADDRESS

E. T. McEnery, M.D., Chicago

The role of streptomycin in the treatment of tuberculosis has been well established. This has been observed from the reports of many authors and from personal experience with a large number of tuberculous children who were treated with streptomycin.

In the fall of 1947, streptomycin therapy was begun on a selected group of 21 children in the Chicago Municipal Tuberculosis Sanitorium. These patients had been under observation for periods varying from 2 months to 36 months, and all of them had positive indications of tubercle bacilli from sputum, gastric washings, or bronchial secretions. The positive sputum tests were confirmed by cultures and guinea pig inoculations. The patients all had positive reactions to Mantoux tests, and roentgenograms showed lung infiltrations of varying degrees. A complete history was taken on each child, with special emphasis on contact with a person having tuberculosis. In all cases, the diagnosis of an active pulmonary process was made before any streptomycin therapy was started.

Each case was closely observed clinically during the course of treatment. Roentgenograms were taken once a month during use of the drug and every two to three months after termination of streptomycin treatment. All the patients were kept on essentially the same rest program. Blood cell counts and sedimentation rates were taken once a month. After streptomycin therapy was stopped, cultures and stained smears of gastric washings and bronchial secretions were made. Two negative examinations of gastric washings and one negative examination of bronchial secretions were required before a child could be discharged from the sanitorium.

TYPES OF TUBERCULOSIS

Of the 21 patients, 18 (6 white and 12 Negro) were classified as having a progressive primary lesion. This is a relatively early lesion, sometimes evident on physical examination by impaired percussion note and suppressed breath sounds, but usually not causing any other changes in physical signs. The roentgenograms show a soft infiltrative process extending out from the hilum to the periphery of the lung, with some enlargement of the hilar shadows. Three cases (in Negroes) were classed as far-

Dr. McEnery is Assistant Professor of Pediatrics, Stritch School of Medicine, Loyola University; Assistant Attending Physician, Chest Clinic, the Children's Memorial Hospital; and Pediatric Consultant, Chicago Municipal Tuberculosis Sanitorium.

advanced adult type of tuberculosis with marked pulmonary involvement. Physical examination revealed impaired resonance, rales, and signs of cavitation. Large cavities seen in the roentgenograms supported the diagnosis of far-advanced pulmonary lesions. These children had failed to respond to bed rest and artificial pneumothorax and had been on a downward course for two years. The ages of the 18 children with primary lesions varied from 8 months to 11 years, while those with the adult type of lesion were 11, 12, and 13 years old respectively. There were 6 white children and 15 Negro children; 9 were boys, and 12 were girls.

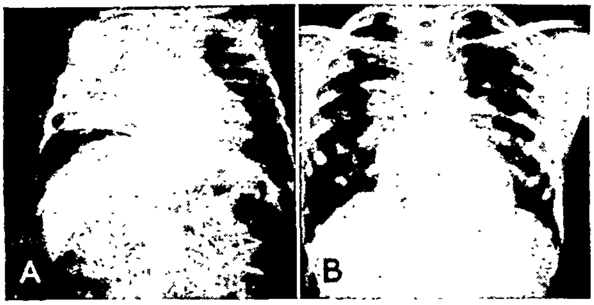

Fig. 1. (case 1).—*A*, roentgenogram showing primary progressive lesion of the right lung in November, 1947, before streptomycin therapy was begun. *B*, roentgenogram taken in November, 1952.

When streptomycin therapy was begun, the majority of the patients received 0.5 gm. in divided doses, twice daily. Later, this was decreased to 0.3 gm., once daily. This dosage was followed for children of all ages and weights. Most of the children received the drug for 120 days; a few received it for 90 days. Blood levels of streptomycin were not checked as a routine procedure, but spot checking on some patients showed adequate therapeutic levels.

Toxic reactions were not seen with the use of these small doses. No auditory or vestibular disturbances were noted during streptomycin therapy, and none developed after the drug was withdrawn. Three patients became resistant to the drug. One of them, a patient with a progressive primary lesion, died of tuberculous meningitis during treatment. Two of the adult type of pulmonary lesions remained resistant to the drug. The initial clinical response to the drug was the same in all cases. This usually occurred in 7 to 10 days. Temperatures returned to normal levels, appetites improved, and there was a definite change in the children's dispositions; they were less irritable and more cooperative.

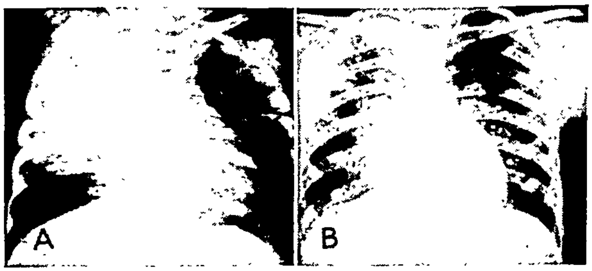

Fig. 2 (case 2).—*A*, roentgenogram showing primary progressive lesion of the right lung in November, 1947, before streptomycin therapy was begun. *B*, roentgenogram taken in November, 1952.

In the instances of progressive primary lesions, even though the general condition of the child improved within 10 days, it was at least a month before any change was noted in the physical findings. In those with the adult type of lesion, the child's appetite improved, and there seemed to be a good general response. The pulmonary process became progressively worse, however, and two of these three children died within a year after streptomycin therapy was begun. The other patient was operated on, and he made an excellent recovery. Changes in the monthly roentgenograms appeared slowly after streptomycin therapy was begun. It was usually three months before a definite change could be detected. Improvement was noted to continue months after streptomycin therapy was discontinued.

PROGRESSIVE PRIMARY LESIONS

Case 1 (fig. 1).—A 7-month-old Negro boy was admitted to Cook County Hospital with a cold. Gastric washings contained tubercle bacilli. The source of infection was unknown. He was admitted to the Municipal Tuberculosis Sanitorium four months later. Physical examination revealed a poorly nourished infant with impaired percussion resonance at the apex of the right lung, with rales and amphoric breathing. His general condition was very poor. The child was given 0.5 gm. of streptomycin daily for 120 days. He remained in the sanitorium until December, 1949, when he was discharged to a foster home. In November, 1952, his general condition was good. There were no unusual physical findings, and the shadows seen on the roentgenograms were minimal on the right side. No relapse had occurred during five years.

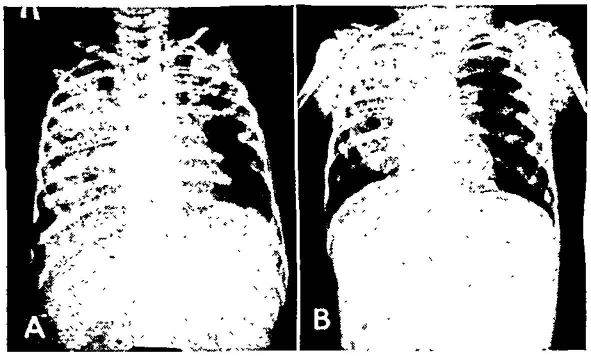

Fig. 3 (case 3).—*A*, roentgenogram showing extensive bilateral lung involvement in February, 1948, when streptomycin therapy was begun. *B*, roentgenogram taken in October, 1948, revealed clearing on both sides with extensive calcification. The patient died of tuberculous meningitis three weeks later.

Case 2 (fig. 2).—A 2-year-old Negro girl had contracted tuberculosis from a cousin. She was transferred from Cook County Hospital to the Municipal Tuberculosis Sanitorium. Gastric washings were positive for tubercle bacilli. The patient was in serious condition. Physical examination revealed impaired resonance over the whole right side, rales, and amphoric breathing. Streptomycin, 0.25 gm. daily, was given for 120 days. This child remained in the sanitorium for six months and was then discharged to her home. In November, 1952, her condition was good. There were no unusual findings on physical examination, and roentgenograms showed only a slight infiltration on the right side. At the present time she is considered a healthy child.

Case 3 (fig. 3).—A 3-year-old white boy was admitted to the Children's Memorial Hospital with what was thought to be a terminal condition, i. e., far-advanced lung disease and draining sinuses in the neck. Physical examination showed a seriously ill, markedly emaciated child with extensive pulmonary lesions. Impaired resonance and breath sounds were present at both right and left lung apexes, with marked involvement at the left base. In addition, rales and amphoric breathing were noted at both apexes. Gastric washings were positive for tubercle bacilli. The patient was given 0.5 gm. of streptomycin four times daily. After 10 days he was transferred to the Municipal Tuberculosis Sanitorium.

On admission the child was very ill and a diffuse erythematous rash covered his body. The pulmonary condition had progressed, and it appeared that the patient would survive only a few days. He was given fluids intravenously and blood transfusions. Because of the rash, streptomycin was withdrawn. After five days the rash faded, and streptomycin therapy (0.1 gm. daily) was resumed. In two weeks the patient's temperature returned to normal, and he began to improve. Changes in the roentgenograms were slow to appear, and the physical findings showed little progress. The sinuses in his neck gradually closed; he gained weight and was ambulant. The course of streptomycin treatment was 120 days. Five months after streptomycin therapy was discontinued he became nauseated, showed other signs of meningitis, and died within two weeks. This child had a progressive primary lesion. The gastric washings remained positive for tubercle bacilli after streptomycin therapy had been discontinued.

At necropsy the lungs showed marked healing of far-advanced, ulcerative tuberculosis. There was cavitation of most of the middle lobe with a residue of calcified, caseous material around the margins and numerous granular concretions in all the interstices of the cavity. The calcified foci appeared to be older than any seen previously in a 4-year-old child. The cavity generally had a smooth wall, some of which was becoming lined with epithelium. The complete autopsy findings showed that considerable healing changes had taken place before meningitis caused the patient's death. The healing was attributed to the effect of streptomycin.

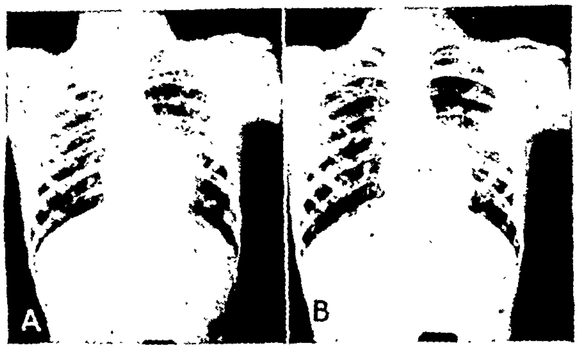

Fig. 4 (case 4).—*A*, roentgenogram taken in November, 1947, before streptomycin therapy was begun. *B*, roentgenogram in April, 1949. The patient died one and a half years after streptomycin therapy was begun.

ADULT TYPE OF LESION

CASE 4 (fig. 4).—A 12-year-old Negro girl had a cough, had lost weight, and felt tired. She was admitted to the Municipal Tuberculosis Sanitorium dispensary. Tubercle bacilli were found in sputum examinations. Physical examinations showed a thin, seriously ill child with cavities at the apexes of both lungs. Bed rest for three months did not arrest the progress of the disease. Streptomycin therapy (0.5 gm. daily) was begun four months after her admission and was continued for 120 days. The patient's course was gradually downhill, and she died a year and a half after streptomycin therapy was begun.

COMMENT

The majority of these children were kept in the sanitorium for a period of one year. They were discharged to their own homes after two gastric washings and a bronchial aspiration were negative for tubercle bacilli on both smear and culture. During the next four years they were examined every six months. Physical examinations were made, and roentgenograms of the chest were taken. All of the children were followed up; three who moved out of the area were given physical examinations by their own physicians.

Mortality in the group has been low; two children with progressive primary lesions died of tuberculous meningitis, one while under treatment and the other after release from the hospital. One child with a primary lesion died after surgery of the lung. Two children with the adult type of lesion died one and two years respectively after drug therapy was started. The drug had little effect on the adult type of lesion. After showing general improvement when streptomycin therapy was begun, these patients had a slow downward course until death. The third patient in this group had lung surgery and made a good recovery. Aside from these cases, none of the children has had a relapse. They have not received any form of medication at home and have lived normal active lives.

On a basis of clinical, roentgenographic, and bacterial observations, improvement that resulted from the original course of treatment has been sustained over a period of at least five years. During this time these children have not received any additional medication, and their activities have not been restricted. The parents cooperated in follow-up study and made an effort to increase the children's daily rest. No special effort was made to keep them on a strict diet.

Primary progressive lesions should be observed long enough to determine if conservative treatment will bring about a suitable response in the pulmonary process. If the lesion is spreading during the period of observation, streptomycin should be given. With the three cases of adult type of lesions the results have not been encouraging. In order to obtain good results in this type of tuberculosis, medical management must consist not only of streptomycin therapy but of combinations of tuberculostatic drugs and surgery if necessary. These measures must be employed before the condition becomes widespread and the prognosis is poor.

CONCLUSIONS

Progressive primary tuberculous lesions in children respond well to streptomycin therapy, and the results obtained during the first year of treatment and observation are well maintained for a follow-up period of at least five years. The seriousness of the adult type of lesion cannot be overemphasized. This type of lesion must be recognized early and must be treated energetically with medical management, rest, pneumoperitoneum, and surgery. Even with these measures, results leave much to be desired.

Pain of Gallbladder Disease.—The pain pattern of gallbladder disease may simulate that of peptic ulcer even to the presence of pain at night and relief by administration of an antacid. Likewise, in exceptional cases, a duodenal ulcer involving the hepatoduodenal ligament is capable of producing enough inflammatory reaction around the common bile duct to produce jaundice. The duodenal ulcer which perforates into the adjacent gallbladder is less common, however, than the large gallstone which perforates the gallbladder and the duodenum to form a fistula.—L. A. Smith, M.D., Pain Patterns in Diseases of the Upper Part of the Abdomen, *Proceedings of the Staff Meetings of the Mayo Clinic,* July 29, 1953.

RADIOACTIVE GOLD IN THE TREATMENT OF MALIGNANT EFFUSIONS

William B. Seaman, M.D., Alfred I. Sherman, M.D.
and
MacDonald Bonebrake, M.D., St. Louis

Since the majority of patients with cancer eventually succumb to their disease, the practicing physician frequently must deal with the problem of palliation. One of the complications of advanced cancer is the accumulation of fluid in the peritoneal or pleural cavities, which not only mechanically interferes with the function of the lungs and gastrointestinal tract but also depletes the body of proteins. Clark[1] reports a 29% incidence of significant effusions (over 1,000 cc. of fluid) in 266 consecutive autopsies on men with malignant disease.

A radioactive isotope was first used to treat ascites due to peritoneal carcinomatosis by Muller in 1945, who used Zn^{63} prepared in a cyclotron. In 1950[2] he reported on eight patients treated by intraperitoneal injection of colloidal Au^{198}, including one in whom both intrapleural and intraperitoneal injections were performed. The inhibition of fluid formation noted in these patients has encouraged other clinical trials. Several reports already published have confirmed the efficacy of this isotope in slowing or stopping the formation of fluid in the pleural or peritoneal cavities. In the small number of cases reported to date, the incidence of favorable results has varied from 30 to 90%.[3]

The mechanism of this therapeutic agent is not clearly understood. Although radioactive gold has both a beta and a gamma emission, the beta particles account for most of the radiation effects produced in the tissues. This is probably a surface phenomenon, since the maximum range of the beta particle in tissue is 3.8 mm. and the average path well under 1 mm. The inhibition of fluid formation might be the result of a direct effect on the cancer cells, since Goldie and Hahn[4] have demonstrated that the intraperitoneal injection of radioactive gold has a lethal effect on free floating sarcoma cells in the peritoneal fluid of mice. Andrews and associates[3a] have observed the disappearance of free tumor cells from fluids following gold therapy in human subjects. On the other hand, the mechanism could be a nonspecific effect resulting from the production of pleural and subpleural fibrosis. Knisely and Andrews[5] have described the characteristic histological findings following radioactive gold therapy as consisting of fibrous thickening of pleura or peritoneum with a layer of fibrin on the surface. Frequently tumor cells could be identified very near the surface. Obliteration of the pleural space was not a constant finding.

The handling of amounts of radioactivity involved in this type of therapy is potentially hazardous and should be carried out only by personnel familiar with the dangers and methods of protection. The details of technique and handling have been published elsewhere.[6]

This report is based on 74 patients who have been treated with Au^{198} for metastatic cancer in either the peritoneal or the pleural cavities or both (table 1). In this group are two patients with proved malignant pericardial effusions that have not been previously described in the literature. This series has been divided into two groups, pleural and peritoneal, which will be discussed and evaluated separately. Eight patients received both intrapleural and intraperitoneal gold and were included in both groups.

TABLE 1.—*Results of Therapy with Au^{198}*

No. surviving over one month	26	27
No. surviving over six months	9	15
No. lost to follow-up	3	0
No. with palliation achieved	20	20

PLEURAL EFFUSIONS

A total of 40 patients with malignant pleural effusions were treated with radioactive gold during the period of July, 1951, to May 1, 1953. All of these were patients with proved cancer, and in most the malignant nature of the effusion was confirmed by the demonstration of malignant cells in the pleural field. We do not believe that every patient with a malignant effusion is necessarily a candidate for radioactive gold therapy. Since the main therapeutic effect is the inhibition of fluid formation, therapy is usually not indicated unless the patient is experiencing respiratory embarrassment attributable to the presence of fluid and repeated thoracenteses have demonstrated the rapid reaccumulation of the effusion. The dose used in almost all instances was 100 mc. The gold used in this laboratory is calibrated by a gamma ray comparison to a radium source. This measurement is performed by means of a modified Lauritzen electroscope. It should be noted that the values obtained do not agree in general with the calibration supplied by the Abbott Laboratories, our values running approximately

20% higher. Thus, a dose of 100 mc. according to our calibration corresponds to about 80 mc. as supplied by Abbott Laboratories.

In five patients bilateral intrapleural injections of radioactive gold were given. In two instances this was done at a single sitting, in two others a week intervened between the two injections, while in the fifth patient a right pleural effusion was treated with radioactive gold nine months following similar therapy for a left pleural effusion. Re-treatment of the same side was done in two cases. One patient in whom 75 mc. of Au^{198} inhibited fluid formation for three months was re-treated with 100 mc. and required no further thoracenteses until she died five months later. Another patient was re-treated three months after a first injection had failed to control the effusion. The second treatment is too recent to evaluate satisfactorily.

Eight patients received radioactive gold in the peritoneal and pleural cavities. In five patients with ovarian tumors, both the pleural and peritoneal effusions were controlled in three while in the other two only the ascites were controlled. Two patients with a generalized lymphoma and a gastric cancer, respectively received benefit from the intrathoracic injection but none from the abdominal injection. One patient received no benefit from either the peritoneal or intrapleural gold.

Some patients may continue to accumulate fluid for several weeks and still have a favorable response. The injected gold apparently becomes fixed to the serous surfaces, since measurements of radioactivity of pleural and ascitic fluid reveal that in six to seven days there is only 5 to 10% of the initial radioactivity remaining even after correction for the radioactive decay.[7] Because of the rapid decay and this fixation phenomenon, very little of the radioactivity is lost after one week if a repeat thoracentesis is necessary for relief of symptoms. The following case report illustrates an excellent response to radioactive gold therapy.

REPORT OF A CASE

CASE 1.—A 50-year-old woman had a left radical mastectomy in January, 1950, for breast cancer. In July, 1952, the onset of dyspnea and left chest pain resulted in the discovery of a left pleural effusion (fig. 1*A*). During the subsequent nine days, three thoracenteses were performed with the removal of a total of 4,800 cc. of grossly bloody fluid. On July 28, 1952, 100 mc. of Au^{198} were injected into the left pleural space. The patient improved markedly and her dyspnea completely disappeared. A chest roentgenogram in December, 1952, five months later showed pleural thickening and a small pleural effusion or pleural thickening in the left costophrenic angle (fig. 1*B*). The last roentgenographic examination in April, 1953, showed the development of a right pleural effusion and mediastinal adenopathy but no change in the appearance of the left side of the chest.

The result of this type of therapy as given in table 1 shows that some palliation occurred in about half of the entire group. The achievement of palliation was based solely on inhibition of fluid formation. This was difficult to determine in the 11 patients who died within one month of treatment. Of the 26 patients who survived longer than one month, significant palliation was accomplished in 20. Three patients were lost to follow-up. There seemed to be no relation between the site of the primary tumor and the response to therapy (table 2).

PERICARDIAL EFFUSION

Two patients with malignant pericardial effusions associated with clinical evidence of cardiac tamponade were treated with radioactive gold. One patient was a man with a carcinoma of the lung in whom the intrapericardial injection of 90 mc. of Au^{198} failed to prevent the rapid reaccumulation of fluid although injection of 100 mc. into the left pleural space did inhibit pleural fluid formation. The other patient had an excellent response Since treatment of malignant pericardial effusions with radioactive colloidal gold has not been previously reported, the second case is briefly described.

TABLE 2.—*Results in Intrapleural Effusions Treated with Au^{198}*

Source of Primary Lesion	No. of Patients	No. Survived Over 1 mo.	No. Survived Over 6 Mo.	No. with Palliation Achieved

Ovary	7	5	2	4
Lymphoma	5	3	2	2
Nasopharynx	1	1	0	1
Stomach	1	1	1	1
Unknown	2	1	0	0
Total	40	26	9	20

CASE 2.—A 55-year-old white woman entered Barnes Hospital because of increasing dyspnea, orthopnea, and ankle edema of three weeks' duration. Twelve years earlier a right radical mastectomy had been performed for breast cancer Examination disclosed a weak, cyanotic woman with severe orthopnea, venous distention, hepatomegaly, and ankle edema. The heart sounds were of fair quality, but a pulsus paradoxicus was present. There were enlarged hard lymph nodes in the left axilla, left supraclavicular region, and the cervical region bilaterally. The venous pressure was 320 mm. of water. Chest roentgenograms revealed a large heart with poor pulsations and a small left pleural effusion (fig. 2*A*). A pericardial tap removed 20 cc. of grossly bloody fluid, and 20 cc. of air was injected. A subsequent chest roentgenogram confirmed the pericardial location of the fluid and air. Malignant cells were identified in the pericardial fluid. Because of the rapid reappearance of pericardial fluid following repeated pericardial aspirations with signs of cardiac tamponade, 100 mc. of Au^{198} were injected into the pericardial sac on Nov. 8, 1952. The patient gradually improved and was discharged one week after treatment.

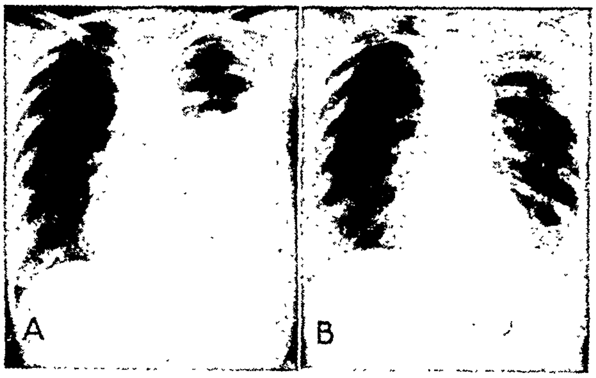

Fig. 1 (case 1).—*A*, chest roentgenogram demonstrating a massive left malignant pleural effusion. *B*, chest roentgenogram five months after the intrapleural injection of 100 mc. of colloidal radioactive gold.

---

[7] Andrews, G. A.; Root, S. W., and Kniseley, R. M.: Metabolism and Distribution of Colloidal Au^{198} Injected into Serous Cavities for Treatment of Effusions Associated with Malignant Neoplasms, Cancer 6: 294 (March) 1953.

A reexamination 10 weeks after hospital discharge revealed a heart of normal size, with regular heart sounds of good quality. Orthopnea had completely disappeared and the patient complained only of mild exertional dyspnea. There was no ankle edema. A chest roentgenogram showed no abnormalities (fig. 2*B*). The patient was last seen on March 24, 1953, four and one-half months, following the radioactive gold therapy. At this time the chest roentgenogram was still negative, and the patient complained chiefly of symptoms referable to enlarging bilateral cervical nodes.

ASCITES

Forty-two patients with ascites have been treated with radioactive gold, including eight patients in whom malignant effusions in both chest and abdomen were treated. The presence of cancer was confirmed in all of this group by either the demonstration of cancer cells in the ascitic fluid or by biopsy at the time of surgery. In 37 patients a laparotomy was done. In the remaining five cases the disease was considered to be too far advanced to justify laparotomy.

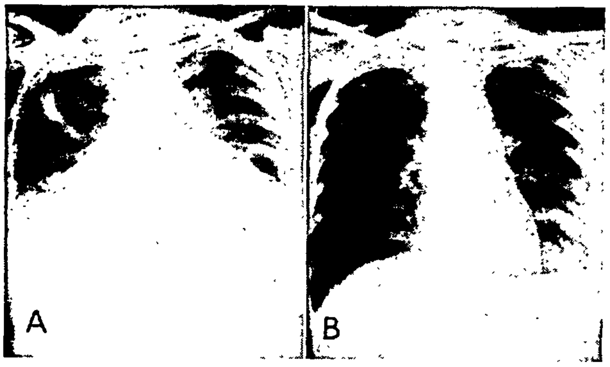

Fig. 2 (case 2).—*A*, chest roentgenogram at time of hospital entry showing cardiac enlargement due to a malignant pericardial effusion. *B*, chest roentgenogram 10 weeks after the intrapericardial injection of 100 mc. of colloidal radioactive gold showing the normal appearance of the heart and lungs.

The sites of origin of the tumors producing an accumulation of fluid in the peritoneal cavity are presented in table 3. Cancer of the ovary was the most frequent cause of ascites in this group, being present in 28 patients (66%). Other causes of ascites were cancers arising in the stomach, rectum, gallbladder, and endometrium.

TABLE 3.—*Results in Ascites Treated with* Au^{198}

Source of Primary Lesion	No of Patients	No. Survived Over 1 mo.	No. Survived Over 6 Mo.	No. with Palliation Achieved
Ovary	30	21	13	16
Endometrium	2	2	0	1
Stomach	5	1	1	1
Gallbladder	1	0	0	0
Rectum	1	0	0	0
Lymphoma	1	1	1	1
Breast	1	1	0	1
Mesothelioma	1	1	0	0
Total	42	27	15	20

Follow-up studies on this group clearly indicate the poor prognosis of persons with malignant abdominal effusions. Only 24 were still alive at the end of one month; six months after the development of ascites 15 were still alive. Many patients were considered to be in terminal condition at the time of treatment, and 13 did not survive one month. The achievement of palliation was based solely on the inhibition of fluid formation, which was difficult to evaluate in those who died within one month. Of 27 patients who lived longer than one month, 20 (74%) were helped by the treatment. This included 16 of 21 patients with ovarian cancer, 1 of 2 with endometrial cancers, one who is still surviving with gastric cancer, and one patient with a retroperitoneal lymphoma.

The latent period between the diagnosis of the malignant disease and the onset of ascites has been studied and was found to be quite variable. This was also true for the rate of fluid formation. Five patients were asymptomatic for six months following surgery and roentgen therapy. When ascites appeared it reaccumulated so rapidly that paracenteses were necessary at weekly intervals. These patients were then treated with radioactive gold, and fluid accumulation was retarded for as long as four to six months. One patient remained subjectively well for 18 months when ascites developed. After treatment with 150 mc. of gold, she remained well for four months, at which time an additional 75 mc. of gold resulted in three more months of palliation. Twenty-four of the 30 patients with ovarian cancer had received previous external roentgen therapy that had failed to inhibit the production of ascites.

COMMENT

This mode of therapy has been well tolerated by the patients in almost all instances. No significant amount of radiation sickness has been encountered. A few patients have complained of mild nausea and anorexia of several days' duration. A low grade fever occurred in several patients following the intrapleural injection of gold but its causal relationship to the therapy was obscure.

A potentially serious effect of the gold is depression of hematopoiesis. A small portion of the gold gets into the blood stream from which it is removed by the liver, spleen, and bone marrow. This fraction plus the irradiation of the bone marrow by the gamma emissions may result in bone marrow depression. Botsford and coworkers [8] reported four cases of aplastic anemia following therapy with radioactive colloidal gold. In three of these patients the gold was administered by direct injection into a tumor mass while the fourth patient was treated by an intraperitoneal injection. In the autopsy studies of Knisely and Andrews [5] on patients treated with radioactive gold, bone marrow damage was not prominent. In our group of patients, the only hematological damage noted clinically was a mild leukopenia.

Patients should be hospitalized for this procedure so that precautions regarding radiation hazards may be observed. Hospitalization is required for all patients while they harbor more than 30 mc. of activity.[9]

The dosage actually delivered to the serous membranes varies according to the area covered, the depth to which it is covered, and the degree of dilution by the effusion remaining after the aspiration. Injection of gold into a loculation will result in a very high dosage while other areas receive no irradiation. The intraperitoneal injection of 100 mc. into the average adult peritoneal surface of 30,000 sq. cm. results in an average surface dose of about 3,000 rep, assuming it was all evenly distributed over the surface.[7]

[9] Isotopics: Announcement of The Isotope Division, U. S. Atomic Energy Commission, **2:** 3 (July) 1952.

SUMMARY AND CONCLUSIONS

The use of radioactive gold in the treatment of malignant pleural and peritoneal effusions in 74 patients is reported. About half of the entire group received palliation as determined by the inhibition of fluid formation. In the group of patients who lived longer than one month, distinct palliation was achieved in about 75%. Response to treatment was influenced by neither the site of the primary tumor nor the location of the effusion.

AVULSION OF THE BRACHIAL PLEXUS

REPORT OF SIX CASES

Rudolph Jaeger, M.D.,
and
William H. Whiteley, M.D., Philadelphia

The purposes of this paper are to report six cases of avulsion of the brachial plexus from the spinal cord and to direct attention to a diagnostic method for determining the precise location of the traumatic lesion. Often there are no visible signs of trauma to guide the examiner in determining the exact anatomic site of the nerve disruption. The most careful neurological examination fails to disclose, with certainty, the exact point of injury or to explain the nature of the injury present. The six following case reports illustrate nerve root avulsion from the cervical spinal cord, four of them proved by exploratory laminectomy.

REPORT OF CASES

CASE 1.—A 26-year-old Negro woman jumped from an automobile traveling 70 miles per hour seven months prior to her admission to Jefferson Hospital on May 27, 1946. She had sustained a laceration of the left scapuloclavicular region and a scapular fracture. There was immediate and complete paralysis of the left arm that remained unchanged. Examination revealed complete paralysis and atrophy of all the muscles of the left shoulder girdle, arm, forearm, and hand. There also was total anesthesia of the limb except for the second thoracic dermatome beneath the axilla. Horner's syndrome was present. Roentgenograms of the cervical spine, dorsal spine, and left shoulder revealed only osteoporosis of the bones of the shoulder.

It was concluded that an exploratory cervical laminectomy was advisable to determine the possibility of root avulsion from the cord and to render a more decisive prognosis. On June 6, 1946, the laminar arches of the fourth, fifth, sixth, and seventh cervical and (partially) of the first thoracic vertebrae were removed. On opening the dura no motor or sensory roots were seen coming off the left side of the spinal cord over this distance (fig. 1). They had been completely avulsed from the cord leaving only the torn foramens in the dura where they normally pierced it. These foramens had healed across. The cord itself did not appear to be damaged by the trauma, but there was no sign whatsoever of any motor or sensory roots reaching from the fourth cervical to the first dorsal segments. The roots on the right side were normal. The sixth cervical root on the left side was explored extradurally (through the foramen), and the avulsed ends were found about one-half in. (1.27 cm.) lateral to the dura.

CASE 2.—A 19-year-old Negro girl was thrown about 30 ft. (9 m.) during an automobile accident on April 14, 1947. She sustained superficial lacerations and complete paralysis of the right arm. On admission to Jefferson Hospital four months later, examination revealed atrophy of the right shoulder girdle and upper arm. The right forearm was moderately atrophied, and there was edema in the right hand. There was paralysis of the muscles of the right shoulder girdle (with scapular winging), the right arm and forearm (with wrist drop), and of all radially innervated muscles in the right hand. There was no paralysis of median or ulnar innervated hand muscles. There was hypalgesia in the fifth and sixth cervical dermatomes over the lateral aspect of the right arm and in the median and radial zones in that hand. Roentgenograms of the cervical spine and shoulders showed only a subcoracoid subluxation of the right humerus.

It was decided to explore the cervical spinal cord for prognostic reasons. On Sept. 5, 1947, right cervical hemilaminectomy was performed from the 4th to the 7th segments. The dura over this region was found torn at the exit of each nerve through it. The dura was opened, revealing that the sensory and motor roots had been completely avulsed from the spinal cord throughout the uncovered length. This included the fifth, sixth, and seventh nerves. It is possible that the roots below were avulsed also, but these were not uncovered. The spinal cord was perfectly denuded of all remnants of nerve fibers. The picture was that of a complete pulling away of the motor and sensory roots along with a portion of dura about 5 to 8 mm. in diameter at each spinal segment.

CASE 3.—A 28-year-old man was involved in a sledding accident 12 years before admission in which his head and left shoulder struck a tree. He was knocked unconscious and awoke one week later with complete paralysis of the left arm and numbness of the left hand. After the first two years strength gradually returned so that, on examination in April, 1948, he had a complete wrist drop, triceps paralysis, severe weakness of the deltoid and pectoral muscles, and moderate weakness of the supraspinatus, serratus magnus, rhomboid, brachioradialis, teres, and hypothenar muscles. There was anesthesia over the lateral aspect of the upper arm and forearm and over the radial zone in the hand. The biceps and triceps reflexes were absent. Subluxation of the humeral head was present.

On April 19, 1948, the left brachial plexus was explored above the clavicle and in the axilla. The middle trunk was healthy and of normal size. It was stimulated, but there was no muscular response. The upper and lower trunks were stimulated with violent, muscular reaction. The cords were then explored in the axilla; there was absence of electrical response from the posterior cord. Presumably the lesion was above the level of exploration and could be assumed to be an avulsion from the spinal cord.

CASE 4.—A 17-year-old Negro boy fell from a truck five months prior to admission to Jefferson Hospital on Sept. 11, 1951. He landed on his head and left shoulder and sustained immediate, continued, complete paralysis of the entire left upper limb and shoulder girdle. There was complete sensory loss from the fifth through the eighth cervical dermatomes. Severe atrophy was present in all muscle groups of the useless limb. The level of the lesion was at the spinal cord itself (fig. 2), similar to the description of the roentgenograms obtained by

---

From Jefferson Medical College and the Department of Neurosurgery, Jefferson Hospital.

Murphey and Kirkland.[1] Significantly, there was no Horner's syndrome or any other spinal cord signs that would indicate such a central site of nerve disruption. The accurate prognosis afforded by the myelographic demonstration of an incurable lesion enabled us to transfer the patient to the orthopedic service. The useless limb was amputated in November, 1952, thus ridding the boy of an unsightly, burdensome member and facilitating his rehabilitation.

Case 5.—In August, 1952, a 19-year-old youth fell 30 ft. through a trap door and landed on his left shoulder and knee. He sustained immediate paralysis and numbness of the left upper limb; this was unchanged when he was first seen eight weeks after the accident. Examination disclosed complete paralysis and muscle atrophy of the entire left upper limb, with absence of tendon reflexes, and anesthesia from the fifth cervical through the first thoracic dermatomes. A cisternal cervical myelogram with ethyl iodophenylundecylate (Pantopaque) showed no abnormalities.

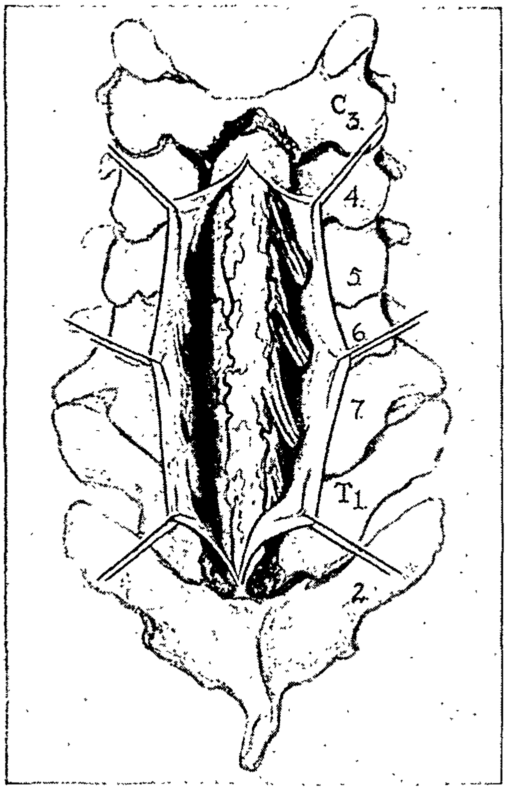

Fig. 1.—Operative appearance of cervical spinal cord showing avulsion of both motor and sensory nerve roots on the left side (case 1). Normal root outlets greatly enlarged by the avulsed roots carrying with them a button of the surrounding dura.

In order to confirm our clinical impression hemilaminectomy was performed on Oct. 24, 1952. The fifth, sixth, and seventh cervical and first thoracic laminas were removed. The fourth, fifth, sixth, and eighth cervical and first thoracic roots were normal, but the seventh cervical roots had been avulsed from the spinal cord (except for one hair-thin nerve filament) and had disappeared out of the dural foramen, which was virtually an empty hole (fig. 3). Both motor and sensory roots were involved. There was no evidence of spinal cord damage or scar where the root had been joined to the cord. Four months later, sensation had returned down to a point just below the elbow, but complete paralysis was still present. This patient may continue to improve over the course of the next two years in view of the small amount of known permanent nerve damage.

Case 6.—A 53-year-old Negro woman fell down three steps on Dec. 31, 1952, and landed on her left shoulder. There was immediate paralysis of all movements at the left shoulder, which remained unchanged at the time of her admission to Jefferson Hospital two weeks later. Examination showed paralysis of the supraspinatus, deltoid, pectoral, biceps, and brachioradialis muscles, and pronator and supinator muscles of the wrist. The latissimus dorsi and triceps muscles were weak. Appropriate atrophy was present. There was subluxation of the humeral head. The biceps and triceps reflexes were absent. There was no sensory loss. Hand function was good. Cisternal

[1] Murphey, F., and Kirkland, J. W.: Myelographic Demonstration of Avulsing Injuries of the Brachial Plexus, read before the Clinical Congress of the American College of Surgeons, Chicago, 1949.

cervical myelogram was done with normal results. Exploratory cervical hemilaminectomy was performed on Feb. 2, 1953, exposing the fifth cervical through the first thoracic roots intradurally on the left side. The fifth motor root was completely absent, since it had been avulsed from the cord (fig. 4). The sixth and seventh motor roots were grey and edematous. All the other roots of the brachial plexus were normal. Electrical stimulation of the affected roots produced motor responses at only such a high intensity of current that we assumed overflow of current to be responsible. Two weeks later arthrodesis of the shoulder was performed by the orthopedic department. Five weeks thereafter a Steindler transfer of the wrist flexors was performed to obtain flexion at the elbow. Although there was considerable return of pectoral function, it was assumed that further recovery was unlikely.

COMMENT

The brachial plexus originates from the spinal cord by means of the anterolaterally placed motor and posterolaterally placed sensory root filaments. At its point of origin, each root is disseminated on the cord into numerous, almost microscopic fibers. This continuous row of nerve root filaments extends the entire length of the cord. At every segmental level, a number of these filaments converge as the anterior (motor) and posterior (sensory) roots of the spinal cord before they pierce the dura to become the mixed spinal nerves. The brachial plexus is then formed from the undivided, anterior, primary rami of the fifth, sixth, seventh, and eighth cervical and first thoracic nerves, with possible minor contributions from the fourth cervical and second thoracic nerves.

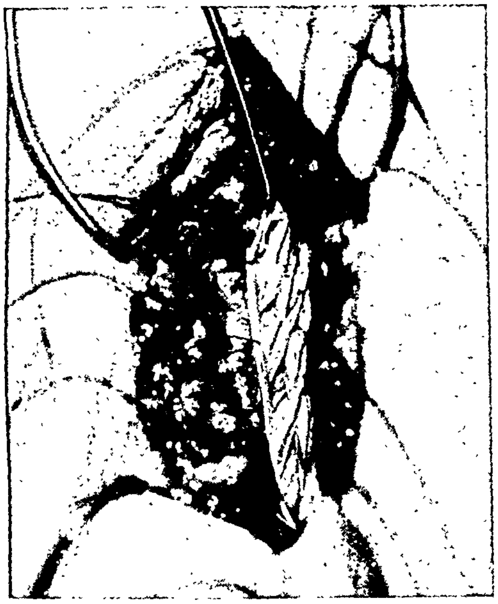

Fig. 4.—Operative view of hemilaminectomy showing (nerve hook) fifth sensory root; note complete absence of fifth motor root, greyish appearance of sixth and seventh motor roots, and normal appearing eighth sensory and motor roots. Black silk ligatures around the sixth, seventh, and eighth sensory roots.

It can readily be seen from this structural arrangement that the major resistance to any avulsive force applied to the brachial plexus must be exerted by the spinal dura at the foramens where the roots pass through this structure. Once this resistance, which is considerable, is reduced, there remain only the extremely weak, microscopic filaments with little actual strength to withstand a complete tearing of the nerve roots from the cord at the cord.

Any injury of the roots themselves will usually be manifested by: (1) Horner's syndrome, if the first thoracic root is affected; (2) paralysis of the rhomboid, levator scapulae, and serratus anterior muscles, if the fifth, sixth, and seventh roots are affected, insomuch as the dorsal scapular and long thoracic nerves arise prior to the trunks; and (3) possible signs of spinal cord damage, if the roots are avulsed from the cord itself. More distal paralyses and sensory deficits in the myotomes and dermatomes supplied by the affected roots will also be present. It is important to recognize any signs indicating the nerve roots themselves as the site of the lesion, since it is worthless to attempt nerve repair at this location, to render an accurate prognosis. It is obvious that the prognosis in nerve root avulsion is hopeless. Rehabilitative surgery, such as amputation, arthrodeses, or tendon-muscle transfers, can be done at the earliest possible opportunity.

There is almost nothing in the medical literature to indicate any actual observation of the spinal cord denuded of its nerve roots in the pathogenesis of brachial plexus avulsion. Loyal Davis [2] noted, in a study of 47 cases of brachial plexus injuries, that in only 2 cases was complete avulsion of the roots from the spinal cord observed, and it was associated with other lesions of the spinal cord. In these cases extraspinal exploration of the plexus [3] was done, whereas we chose direct inspection by laminectomy.

Murphey,[1] in 1949, presented his experiences with the radiographic demonstration of brachial plexus root avulsions by cervical myelography with iodized oil. He discovered, by roentgenography, "a pseudomeningocele or a diverticulum-like structure extending through the intervertebral foramen into the brachial plexus." In some cases, there was only distortion of the lateral extension of the nerve root sleeves. He studied seven cases in this way and verified the diagnosis in three cases by extraspinal operation. Although the myelogram cannot be relied on to reveal the degree of root damage, it can demonstrate that the lesion is intraspinal in location; furthermore, in the two cases in which we did both myelography and laminectomy, there was a disparity between the results of each. In one case (case 5), the myelogram appeared to be normal, and yet at operation the seventh motor and sensory roots were found avulsed. In another instance (case 6), the myelogram again showed no clear-cut evidence of root avulsion. At operation, not only was one (motor) root actually avulsed but two more roots were badly damaged; yet this damage could not be visualized by myelography. Unless the myelogram reveals profound root disruption, the spinal cord and its roots must be exposed surgically for accurate assessment of the damage.

SUMMARY AND CONCLUSIONS

We have demonstrated, by hemilaminectomy, the actual conditions in avulsion of the cervical nerve roots from the spinal cord. It is valuable to utilize cervical myelography and possibly hemilaminectomy in all nonpenetrating injuries of the brachial plexus in order to determine prognosis or any need for extraspinal neurorrhaphy or rehabilitative procedures.

CLINICAL NOTES

LATE MENINGEAL REACTION TO ETHYL IODOPHENYLUNDECYLATE USED IN MYELOGRAPHY

REPORT OF A CASE THAT TERMINATED FATALLY

Theodore C. Erickson, M.D.
and
Hans J. van Baaren, M.D., Madison, Wis.

Ethyl iodophenylundecylate (Pantopaque) has been employed extensively as a contrast medium in myelography since it was first introduced about 10 years ago. Its widespread use is evidence that severe reactions are uncommon, and in our experience ethyl iodophenylundecylate has proved to be a most satisfactory medium. We had observed only transitory and minimal reactions until the case herein reported came to our attention. This case is noteworthy for several reasons. The serious complications were so long delayed (15 months) after the use of ethyl iodophenylundecylate in myelography that it might easily have been overlooked as an etiological factor. The fatal termination was due to intracranial arachnoiditis, as a result of inadvertent introduction of the ethyl iodophenylundecylate into the basal cisternae during myelography. This emphasizes the importance of employing proper technique to avoid such an occurrence.

REPORT OF A CASE

A 33-year-old man was admitted to the hospital on Dec. 22, 1949, complaining of weakness of his legs, which he had first noticed in 1947 and which had gradually become worse until he had great difficulty in walking. He felt a tingling sensation in his legs and noted a decrease of the urinary stream. His past history was not relevant, except that he had had frequent "sinus trouble" and had had a goiter in childhood, which had been treated with iodine.

The results of the physical examination were essentially normal. Findings on neurological examination were absence of the lower abdominal and cremasteric reflexes, hyperactive patellar reflexes, and bilateral positive Babinski's reflexes. There was a slight diminution of vibration sense in the lower extremities and diminution to pinprick over the scrotum and penis. There was spastic paralysis of both lower extremities. The results of the urinalysis and routine blood studies were normal. The sedimentation rate was 4 mm., fasting blood sugar 85 mg. per 100 cc., and the nonprotein nitrogen 40 mg. per 100 cc. The blood Wassermann reaction was negative. X-ray films of the dorsolumbar spine revealed a moderate amount of marginal spurring on the anterior borders between the eighth and ninth thoracic vertebrae. There were only four vertebrae with true lumbar characteristics, and there was a spina bifida cleft at the arch of the first sacral segment. The spinal fluid pressure in the recumbent position was 210 mm. of water, and with compression of the jugular veins it rose to 430 mm. and fell promptly to 180 mm. The spinal fluid was clear and colorless, with no blood cells, a protein level of 24 mg. per 100 cc., and negative Wassermann and Lange reactions.

On Dec. 27, 1949, a myelogram was made, with the injection of 6 cc. of ethyl iodophenylundecylate in the lumbar subarachnoid space. The entire spinal canal was examined, and the appearances were considered within the limits of normal. There is no record on the chart that the ethyl iodophenylundecylate was removed. On the day after myelography the patient's temperature was elevated to a maximum of 102.2 F. He complained of some headache and of a flushed face. On the second day after the myelography the highest temperature recorded was 99.2 F, and by the third day the temperature had returned to normal.

An exploratory laminectomy was done on Jan. 10, 1950. Numerous tortuous veins were found over the surface, extending from the ninth thoracic to the first lumbar segments, of the spinal cord. It was believed that the patient had an angioma. After coagulation of one of the large veins leading to the angioma occurred, the dura mater was closed with nonabsorbable surgical sutures. The wound healed by primary intention, convalescence was uneventful, and the patient said that he had more feeling in his legs, especially for heat or cold, than he had before the operation. He was discharged from the hospital on Jan. 28, 1950, with the diagnosis of hemangioma of the spinal cord.

The patient was seen again as an outpatient on May 12, 1950, when he exhibited considerable improvement in his ability to walk but complained of occasional generalized headache. Almost a year later, April 6, 1951, he returned with a multitude of complaints referable not only to the lower extremities but to the head and upper extremities. In spite of these complaints, he had been working nine hours a day.

He was readmitted to the hospital on April 15, 1951. At that time his wife stated that his ability to walk had improved after the laminectomy 15 months previously. The recurrent headaches previously noted had increased six months before and had become even severer during the preceding three weeks. He became lethargic, vomited, was incontinent, and was occasionally confused and irrational. No definite weakness of the extremities had been noted by the patient or the family.

Physical examination again did not reveal any abnormalities, but the neurological examination showed that he was disoriented as to time and had a slight nuchal rigidity but no papilledema. The blood pressure was 140/94 mm. Hg, pulse 82 per minute, and respirations 22 per minute. The laboratory results were as follows: urine normal, hemoglobin (photoelectric oxyhemoglobin determination) 16.65 gm. per 100 cc., red blood cells 5,520,000 per cubic millimeter, white blood cells 11,100 per cubic millimeter (89% neutrophils, 2% filaments, 5% lymphocytes, 3% monocytes, and 1% eosinophils), blood sugar 140 mg. per 100 cc., and nonprotein nitrogen 30 mg. per 100 cc. A few days later, on April 17, 1951, more persistent vomiting and pronounced nuchal rigidity developed. X-ray films of the skull on April 17 showed considerable iodized oil scattered in the posterior fossa and some in the cisterns about the sella and in the subarachnoid spaces, particularly in the region of the left island of Reil. No other abnormalities were noted.

Disorientation increased, and the Babinski phenomenon became bilaterally positive. There was flexion of the upper extremities and extension of the lower extremities with spasticity. The patient became semistuporous, and an emergency ventriculogram was made. This showed an internal hydrocephalus, with dilatation of the lateral ventricles, the third ventricle, and the aqueduct and upper portion of the fourth ventricle. The spinal fluid was slightly cloudy and contained 650 mg. per 100 cc. of protein, 650 mg. per 100 cc. of chlorides, and 259 white blood cells per cubic millimeter (65% polymorphonuclear leukocytes and 35% lymphocytes). The ventricular fluid contained 180,000 red blood cells and 313 white blood cells per cubic millimeter, in the same proportion as in the spinal fluid. The ventricular fluid sugar was 81 mg. per 100 cc. and the protein 300 mg. per 100 cc. No organisms were seen on smear or culture of either the spinal or ventricular fluid. Special bacteriological studies for tubercle bacilli and fungi were negative.

A suboccipital craniotomy was performed, at which time a complete block of the lower portion of the fourth ventricle was demonstrated. When this was released, there was a forceful gush of cerebrospinal fluid. Microscopic study of the tissue removed at suboccipital craniotomy showed countless neutrophils and lesser numbers of lymphocytes in the meninges

---

From the departments of neurological surgery and pathology, University of Wisconsin Medical School.

Dr. F. L. Kozelka of the University of Wisconsin supplied the chemical determinations.

and normal cerebellar tissue. There was temporary improvement after the suboccipital craniotomy, but death occurred suddenly two days later.

Postmortem Examination.—No significant abnormalities were found, other than in the cranium and vertebral canal. Since a granulomatous lesion had been suspected, a very careful examination of all organs was performed; however, no evidence of tuberculosis or other granulomatous lesion was found. Examination of the brain revealed flattening of all gyri, narrowing of sulci, and severe hyperemia of all superficial vessels. The basal surface of the pons and medulla was covered with a greenish-gray exudate (fig. 1*A*). When horizontal sections of the brain were made, the ventricles (fig. 1*B*) were found to be enlarged. There was a small area of hemorrhage in the right occipital pole and another in the right hemisphere of the cerebellum, as well as some blood clots in the ventricles, no doubt the result of the surgical procedure. Examination of the spinal cord revealed tortuous, dilated blood vessels and a fibrinous exudate (fig. 2) over the lower thoracic portion of the cord. A section through the medulla (fig. 3*A*) showed it to be surrounded by cellular exudate and consisting of a fine fibrillar network containing many lymphocytes and a few plasma cells, the number of plasma cells varying in different areas. An occasional multinucleated giant cell was seen, as well as some fibroblasts. The cerebral vessels near the surface showed perivascular cuffing mainly with lymphocytes (fig. 3*B*).

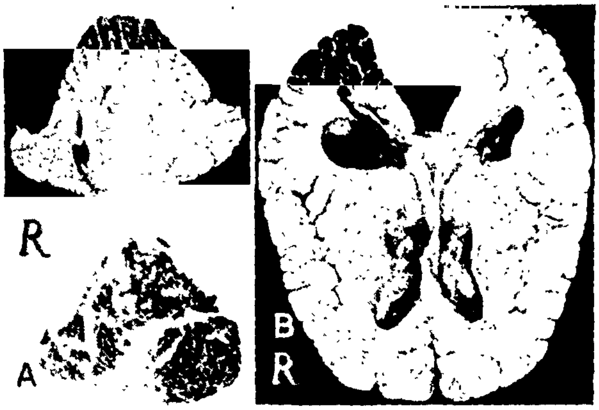

Fig. 1.—Postmortem specimens of the brain. *A*, basal surface of pons and medulla covered with a plastic exudate. *B*, internal hydrocephalus.

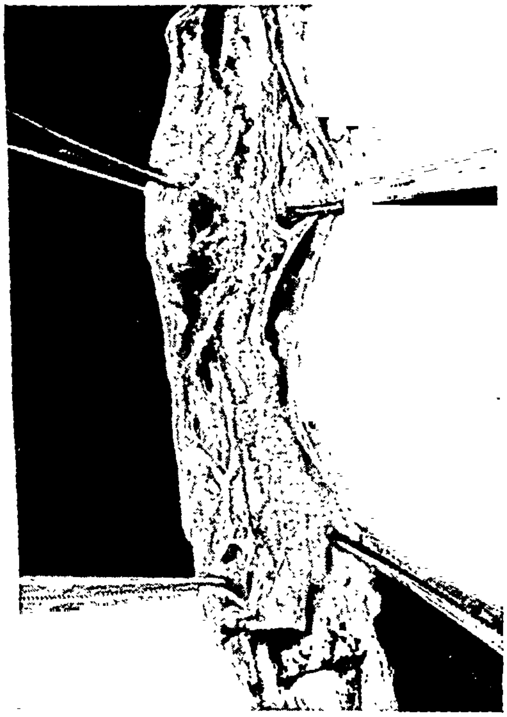

Fig. 2.—Thoracic part of spinal cord.

In addition to the cultures taken during life, the postmortem material was cultured especially for tubercle bacilli and fungi. All bacteriological studies were negative. Smears of the exudate as well as microscopic sections were stained by the following methods: Gram, Ziehl-Neelsen, Kingsley, Mallory's phosphotungstic acid hematoxylin, and Kernohan's stain for Torula, but no organisms were found.

The diagnosis, according to the gross and microscopic picture, was that of arachnoiditis or chronic meningitis, which had produced a severe internal hydrocephalus. The history of the patient, the oil myelography, and the presence of opaque medium on the skull roentgenogram directed our attention to the possibility of a reaction to the iodine in the ethyl iodophenylundecylate. A roentgenogram of the cerebellum and spinal cord taken after death showed areas of increased density in the region of the exudate (fig. 4). For this reason an x-ray photomicrograph (fig. 5) was made of a section through the medulla, which showed areas of greatly increased density corresponding to the meningeal exudate.

Finally, to obtain definite proof of the presence of iodine, material taken from the basal surface of the medulla was examined chemically for iodine. Nearly 50 mg. of iodine per 100 gm. of the material was reported. The total iodine content of the normal body is 20 to 50 mg., of which 50% is in muscle, 20% in the thyroid, 10% in skin, and 6% in skeletal tissue.[1]

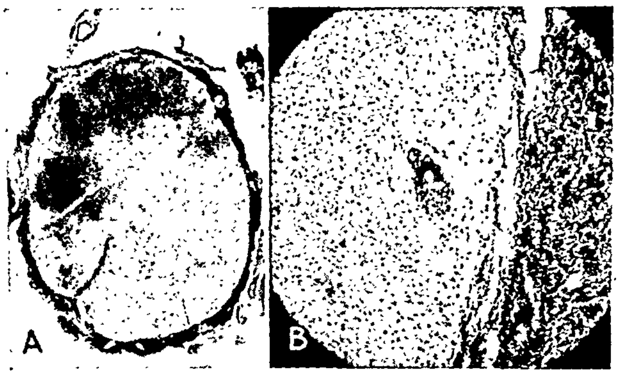

Fig. 3.—Low (*A*) and high (*B*) power view of section through medulla, showing meningitis and encephalitis.

COMMENT

The evidence that ethyl iodophenylundecylate was responsible for the meningeal reaction or arachnoiditis in this patient is both negative and positive. Other etiological agents that might have caused meningitis were excluded by thorough bacteriological and microscopic studies during life as well as at autopsy. The autopsy did not reveal evidence of a possible source of primary infection. Having eliminated, as far as possible, other causative factors, we may consider the evidence that ethyl iodophenylundecylate was responsible. For two days after myelography the patient had a fever, headache, and complained of a flushed face. This immediate reaction, not too unusual, was followed by an apparent quiescent period of nine months, during which the symptoms due to the original spinal cord lesion improved. There would appear to be two possible explanations of this asymptomatic period. The meningeal reaction to the ethyl iodophenylundecylate may have been minimal and only subsequently reactivated by some unknown factor. It would appear more probable that the meningeal reaction was low grade, was slowly progressive, and caused symptoms only when the exudate became extensive enough to produce obstruction to the free circulation of cerebrospinal fluid. The apparent latent period in this case might be considered analogous to that of the pneumonitis following administration of mineral oil. There followed another period of six months of progressively severer headaches and other symptoms, which may be related to the obstructive hydrocephalus that resulted consequent to arachnoiditis. X-ray films of the skull demonstrated ethyl iodophenylundecylate in the intracranial subarachnoid spaces. If the ethyl iodophenylundecylate had not been retained in critical, or bottleneck, areas in the pathways for cerebrospinal fluid circulation, obvious symptoms might not have appeared.

---

[1] Cantarow, A., and Trumper, M.: Clinical Biochemistry, ed. 4, Philadelphia, W. B. Saunders Company, 1949, p. 216.

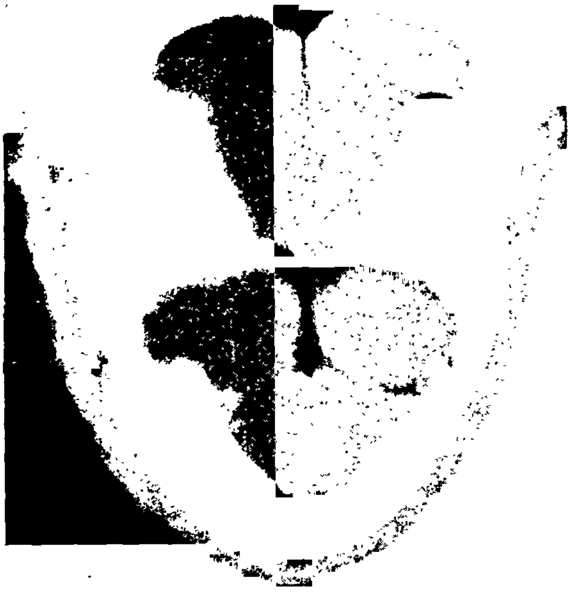

Fig. 4.—Postmortem roentgenogram of medulla, cerebellum, and spinal cord.

There can be little doubt that the meningeal reaction demonstrated post mortem, 15 months after myelography, was caused by the continued presence of the ethyl iodophenylundecylate in the subarachnoid spaces. The distribution of the exudate corresponded to that of the ethyl iodophenylundecylate as revealed in both premortem x-ray films of the cranium and postmortem films of the brain and spinal cord. In addition, the special x-ray studies of microscopic sections demonstrated radiopacity in the subarachnoid exudate that could only result from ethyl iodophenylundecylate. As a final step in establishing the causal relationship, the chemical analysis of the affected meninges showed a tremendous increase of iodine content that can be explained only by the presence of ethyl iodophenylundecylate.

With further survey of our own cases we have not been able to prove any other instances of such severe reactions to ethyl iodophenylundecylate. We continue to employ it routinely, but with the usual safeguards of removing the medium at completion of the procedure and with special care to keep the neck extended so as to prevent its becoming lodged intracranially when the cervical region is examined. Judging by our own experience and that of others, the incidence of reaction is low. In the original experimental work Steinhausen and co-workers [2] did note cyst formation in the subarachnoid space of dogs, and occurrence of slight meningeal reaction to ethyl iodophenylundecylate was noted by Peacher and Robertson.[3] These authors stated, in referring to their case 28, that reaction may occur after an interval if ethyl iodophenylundecylate extends into the basal cisternae. Tarlov [4] observed a pronounced inflammatory reaction, whitish soft stringy exudate of the arachnoid and nerve roots of the cauda equina, at laminectomy 60 hours after 3 cc. of ethyl iodophenylundecylate had been introduced intrathecally, and he termed this reaction "Pantopaque meningitis."

The reports of severe reactions to ethyl iodophenylundecylate have been rare when one considers how extensively it is used. The experimental observations of Steinhausen and co-workers [2] indicated that it provoked less tissue reaction than iodized poppy seed oil. The immediate and late effects of the intrathecal injection of iodized oil were studied by Marcovich and co-workers,[5] and there was a significant case report by Bucy and Speigel in 1943.[6] An early paper on the subject was that of Wartenberg.[7] Lindblom,[8] in an article based

[9] Kennedy, F.; Somberg, H. M., and Goldberg, B. R.: Arachnoiditis and Paralysis Following Spinal Anesthesia, J. A. M. A. 129: 664 (Nov. 3) 1945.

on the use of methiodal sodium (Abrodil) for myelography in 721 cases, reported complications in more than 54. Foster Kennedy and co-workers [9] reviewed the literature dealing with sequelae of spinal anesthesia and reported three cases of arachnoiditis in the spinal region. Other reports of meningeal reaction after spinal anesthesia and the introduction of other agents such as antibiotics intrathecally have appeared from time to time.[10]

Sensitivity or tolerance of the subarachnoid space to these various substances is a matter of relativity. On this score ethyl iodophenylundecylate is no doubt safe, and its margin of safety can be increased by its removal on completion of myelography. The possibility that some reactions may be due to variation in the composition of the ethyl iodophenylundecylate that is supplied has been suggested. Other possible factors such as the introduction of impurities in the syringe or the presence of an idiosyncrasy to iodine must be considered. We have no observations that bear specifically on these problems, but in this case the evidence indicates that the ethyl iodophenylundecylate itself must have been the irritant.

The reaction observed in this case does emphasize the hazard of ethyl iodophenylundecylate being allowed inadvertently to enter the intracranial space. The disclosure of droplets of oil intracranially after myelography is not too uncommon. Often one cannot ascribe any signs or symptoms to their presence, but again the clinical picture may be clouded by the original condition for which the patient was subjected to this examination. The localization of the oil and its amount may be important factors, as was clearly true in this patient in whom an obstructive hydrocephalus was produced due to exudative arachnoiditis in critical areas. Sensitivity to ethyl iodophenylundecylate may be of importance, as may be any underlying disease that contributes to the intensity of the reaction.

That this complication of intracranial extension of the contrast medium can be prevented in the majority of instances by proper technique is well known. Judging by our experience, it still needs to be reemphasized. The indiscriminate use of any method of examination such as myelography by untrained personnel can lead to unnecessary complications. In discussing the injudicious use of myelography, Oldberg [11] made a plea for respect for the tissues of the central nervous system. We would add to this a plea for meticulous attention to details of technique in performing a valuable diagnostic technique such as myelography.

SUMMARY AND CONCLUSIONS

A patient died 15 months after myelography was done with ethyl iodophenylundecylate (Pantopaque), because of an exudative and adhesive arachnoiditis producing an obstruction of the fourth ventricle and basal cisternae. That this meningeal reaction was due to ethyl iodophenylundecylate was indicated by x-ray studies both ante mortem and post mortem, by the chemical determination of iodine in the exudate, and by the microscopic examination. Although such a severe reaction to intracranially administered ethyl iodophenylundecylate is considered very unusual, it would appear that late reactions of milder degree may produce symptoms, the nature of which is overlooked. We would reemphasize the importance of careful attention to details of technique such as removal of the ethyl iodophenylundecylate after myelography and special measures to avoid its introduction into the intracranial subarachnoid space.

MYXEDEMA HEART

ADVANCED FAILURE WITH RAPID RECOVERY

Russell F. Weyher, M.D., Detroit

Recent spectacular surgical therapy in certain cases of heart failure due to congenital anomalies and rheumatic valvular deformities seems to have overshadowed the fact that medical treatment also can produce dramatic improvement in cardiac decompensation from some types of heart disease. Among these, cardiac impairment resulting from thyroid deficiency can apparently be completely corrected. This is not true of the great majority of cases of heart disease, whether medical, surgical, or combined methods of treatment are used. The fact that myxedema in humans can cause diffuse cardiac enlargement, sluggish contractions, and electrocardiographic abnormalities that disappear only after the myxedema is controlled was recorded by Zondek in 1918.[1] Fahr's investigations in this country in 1925 [2] confirmed Zondek's observations and showed that cardiac volume in cases of severe myxedema may be increased 100%. Lerman, Clark, and Means [3] in 1933 showed reduction in the transverse cardiac diameters in 37 out of 48 cases after thyroid therapy.

The following authors have presented cases with serial chest roentgenograms: Schnitzer and Gutmann,[4] Master and Stricker,[5] Schoene and Pollock,[6] Kern and co-workers,[7] Allison,[8] and Ellis and co-workers.[9] None of the cardiac silhouettes in these cases before treatment or before death appear to be as enlarged as that in the case herein reported, although in Schnitzer and Gutmann's case of myxedematous pericardial effusion the cardiac silhouette was nearly as huge in proportion to the chest size.

Presented at the Clinical Conference, Providence Hospital, Detroit, Dec. 21, 1952.

Many patients with cardiac myxedema show varying degrees of pericardial effusion. In the case in this report, the question of effusion in the pericardial sac will doubtlessly occur when the cardiac roentgenographic configuration is studied; however, the patient's collapse after the withdrawal of ascitic fluid made me hesitate to insert a needle through the pericardium. Subsequent progress proved this to be therapeutically unnecessary.

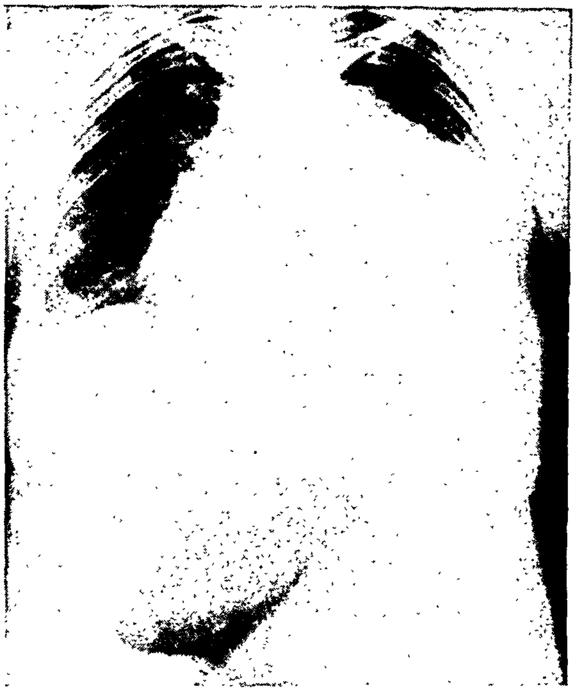

Fig. 1.—Roentgenogram showing cardiac enlargement, particularly on the left, little chronic passive congestion, and gross free fluid.

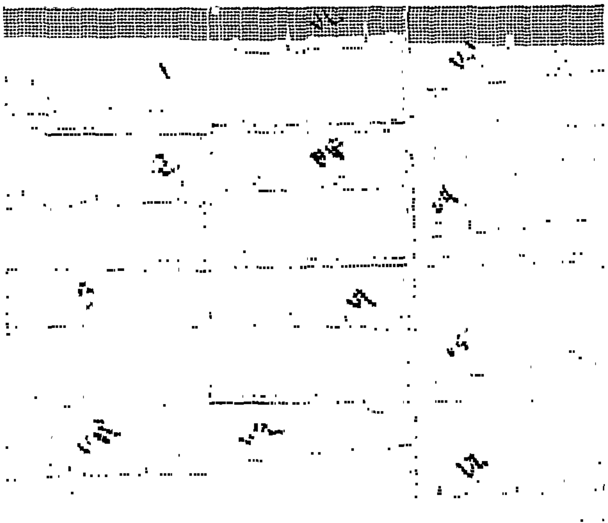

Fig. 2.—Electrocardiographic tracings on Oct. 15, 1951.

Tung[10] has pointed out that in massive pericardial effusion the Q-T interval is normal, whereas White states that in myocardial involvement the Q-T interval is prolonged. In this case, when the patient was first admitted the Q-T interval was 0.38 second, which is within the outer limits of normal for women with this pulse rate. On recovery, however, the electrical systole became considerably shortened (from 0.38 second to 0.28 second) when digitalis was given. There was no fever, no tachycardia, nor any pericardial friction rub heard during this patient's stay in the hospital. Unfortunately, determination of sedimentation rates was never made. Means described the heart in myxedema as characterized by flabby musculature and dilatation of all four chambers, with a reduced minute volume. Advanced congestive heart failure rarely occurs, because with reduction in the heart's capacity for work a parallel reduction occurs in the amount of work it is called on to perform.

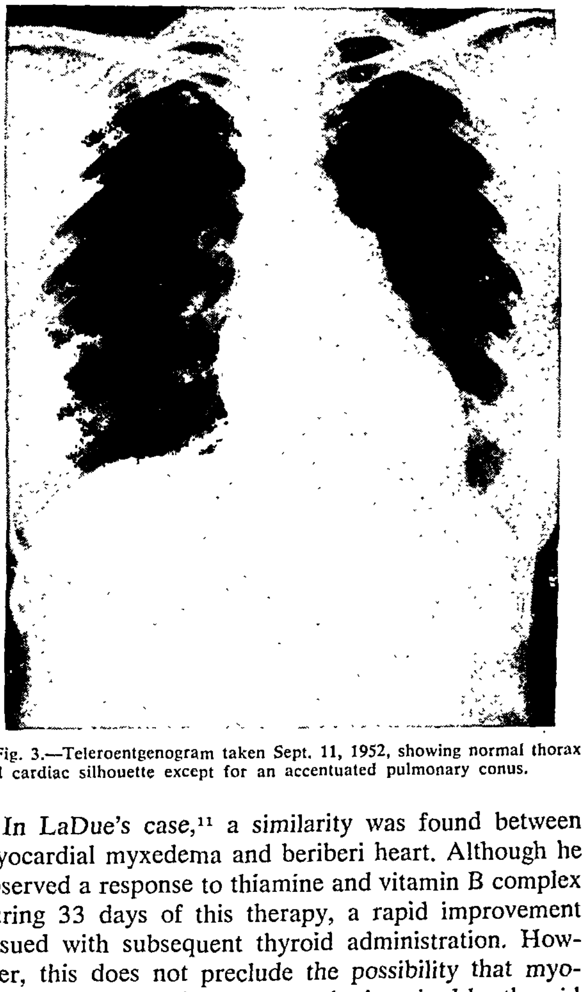

Fig. 3.—Teleroentgenogram taken Sept. 11, 1952, showing normal thorax and cardiac silhouette except for an accentuated pulmonary conus.

In LaDue's case,[11] a similarity was found between myocardial myxedema and beriberi heart. Although he observed a response to thiamine and vitamin B complex during 33 days of this therapy, a rapid improvement ensued with subsequent thyroid administration. However, this does not preclude the possibility that myocardial thiamine utilization may be impaired by thyroid hypofunction, according to Cluxton and co-workers.[12] In this case it was felt that at the start of therapy reduction in intra-abdominal pressure, digitalization, and diuresis were necessary. Next in order, thiamine and thyroid were administered to aid in metabolic recovery of the damaged myocardium. Ten months later it was considered safe to remove a possible focal infection in the calculus in the gallbladder, which may have caused hepatic impairment. On reflection, although the thyroid dosage administered and its rapid increase seemed large, the possible strain on the coronary arteries was felt to be not too hazardous.

REPORT OF A CASE

A 47-year-old white woman was first examined in Providence Hospital on Oct. 9, 1951, having been referred to me by Dr. James Morley, whom she had consulted intermittently the previous summer for shortness of breath and increased size of her abdomen. For the previous two months her waist had felt very tense and she had to lie on three pillows to sleep at night. There was increasing frequency of urination, swelling of the ankles and labia majora on standing or walking, but no pain nor soreness anywhere, including the pericardium.

Her family history showed no evidence of goiter nor other familial diseases. Her husband's health was good, and she had one living child. In 1944 a hysterectomy was performed for "vaginal bleeding." Later that year a thyroidectomy was done for "hypertension and shortness of breath," and this was followed that autumn by an appendectomy. For three years she had had flatulence, "bloating," and indigestion, especially after eating rich or fatty food.

When observed, the patient, a small white woman, lay flat in bed, except for two pillows that raised her head. She was listless, apathetic, and slow to answer questions. There was no apparent discomfort except when she was raised to a sitting position. She then became cyanotic, began to gasp, and showed much distress. The neck veins showed marked distention and increased pulsation, both aggravated when she assumed an erect posture. The pulse rate was 58 beats per minute, the temperature 97.4 F, and the respirations 16 per minute. Her color was sallow, with conjunctival pallor and paleness of the cheeks and tongue. The skin was very dry, rough, and especially thickened over the elbows and knees. The extremities felt cold. Scars were present transversely over the anterior neck, vertically over the midabdomen, and in the right lower rectus region. The cervical lymph nodes were palpable, and a small soft mass was present in the right breast. (This disappeared some months later.) The chest was symmetrical and flat to percussion except in the apices, but diminished excursion was present on the left side. Fine crepital rales were heard throughout the lower two-thirds of both lungs posteriorly. The apex impulse was not felt, and heart sounds were almost inaudible. The abdomen was enormous and tense, and shifting dulness in both flanks was very obvious. No intra-abdominal masses could be palpated. Edema was present in both labia majora, the lower sacrum, thighs, legs, and ankles. Portable x-ray studies the next morning showed gross cardiac enlargement, mainly to the left, with surprisingly little chronic passive congestion and gross free fluid obscuring all details within the abdomen (fig. 1).

The anatomic diagnoses were advanced heart failure with hypertension and massive ascites, with pulmonary congestion and generalized dependent edema. Etiologically the following conditions were considered: (1) advanced rheumatic heart disease, (2) cardiac cirrhosis, (3) intra-abdominal neoplasm, (4) myocardial failure following a coronary occlusion, (5) hypertensive cardiovascular renal insufficiency, (6) heart failure in beriberi, and (7) heart failure in myxedema.

Therapy.—On Oct. 11, the patient was given digitalis and then ammonium chloride, 45 gm. daily, and a sodium-restricted diet. On Oct. 12, Dr. Morley removed 4,500 cc. of straw-colored ascitic fluid through an abdominal trocar. A cell block of the settled fluid showed a nonspecific inflammatory reaction. Immediately after the paracentesis, the patient collapsed and went into shock. The pulse became imperceptible, she became an ashen color, and the blood pressure dropped to 60/20 mm. Hg. Six minims of methamphetamine hydrochloride (Drinalfa) and 250 cc. of blood plasma were administered intravenously, and the patient then recovered. On Oct. 13, 75 mg. of thiamine were given intramuscularly with 0.25 mg. of digoxin daily.

Course.—An electrocardiogram on Oct. 15 showed a sinus rhythm, a rate of 68, with a PR interval of 0.16 second in duration and a QRS interval of 0.06 second. There were inverted T waves in leads 2, 3, and AVF, with diphasic T waves in leads V4, V5, and V6 (fig. 2). The relatively slow pulse (58 per minute on admission) and subnormal temperatures persisted during the patient's entire hospital stay of 30 days. During the last week, however, the daily temperatures tended to rise toward the "normal" chart line.

After the abdominal paracentesis, diuresis occurred and there was some reduction in the edema. The patient remained listless, however, and showed a lack of interest in her surroundings and in her condition. On Oct. 13 the blood pressure was 108/72 mm. Hg. On Oct. 19, 1.5 cc. of meralluride, a mercurial diuretic, was administered. This was repeated two days later and then again every third day. Very little change in the edema occurred. On Oct. 23, 30 mg. of desiccated thyroid extract was administered daily and the dose increased every other day, until by Nov. 1, 90 mg. were being given. At this time the patient's condition rapidly changed. She became alert and vivacious, and practically all of her visible edema disappeared.

On Oct. 24, permission to get out of bed was granted. The blood pressure was 128/80 mm. Hg, the pulse rate 64, and the patient's abdomen was soft, with the liver edge 5 fingerbreadths below the right costal margin. The labia, thighs, and legs showed no edema.

Multiple chest teleroentgenograms taken Nov. 5 were interpreted as follows: "The bilateral passive pulmonary congestion present Oct. 10 has cleared. There is improvement in the general cardiac enlargement. Evidence of left auricular enlargement is still present."

Serial Laboratory Studies

	1951			1952	
	Oct. 10	Oct. 31	Nov. 8	Sept. 9	Dec. 9
Basal metabolism, %	...	−14	1+	22+	10+

Icterus index	...	...	6.2	...	4.1

On Nov. 7, 1951, she was able to sleep horizontally and to walk about in the room and to the toilet without experiencing dyspnea. The next day, the cardiac sounds were regular, with no audible murmurs. The apex beat was in the anterior axillary line, the liver edge was 4 fingerbreadths below the right costal margin when the patient was in the sitting position, and there was no visible edema. She was discharged home with a regimen of 90 mg. of thyroid extract daily and a capsule of a multiple vitamin formula. On Sept. 11, 1952, about 10 months later, she was readmitted to the surgical service. The blood pressure was 140/70 mm. Hg with a normal pulse rate. A teleroentgenogram showed the thorax and cardiac silhouette to be normal except for an accentuated pulmonary conus (fig. 3).

The next morning cholecystectomy was performed by Dr. Frank Porretta, who found a thickened gallbladder containing five faceted calculi with multiple pericholecystic adhesions. When the abdomen was opened, the liver appeared normal, with a sharp axe-like edge. The patient was discharged on the eighth day with an uneventful convalescence.

During her hospital stay six normal routine urinalyses were performed. On Oct. 10, 1951, the fasting nonprotein nitrogen was 37 mg. per 100 cc., and one month later the fasting blood glucose was 103 mg. Initially, the total leukocyte count tended to be slightly low. Fasting blood serum cholesterol estimations were not high in this case, but the values rose somewhat as compensation was established and thyroid extract was administered. This rise may be due to cholesterol mobilization and has been observed in other cases of thyroid deficiency.

On March 12, 1953, the patient was reexamined. She had no complaints. Results of the physical examination were essentially negative, including that of the heart. She was taking 90 mg. of thyroid extract daily, but no other medication. A teleroentgenogram of the chest showed no change from that of September, 1952. The electrocardiogram showed normal graphs, i. e., the previous T wave inversions had become normally upright.

SUMMARY

A case of heart failure associated with myxedema secondary to thyroidectomy and uncomplicated by coronary disease, valvular involvement, angina, or prolonged hypertension, with extreme enlargement of the cardiac silhouette, is presented. In spite of some opinions that such hearts will not respond to conventional therapy before thyroid is given, this patient showed excellent response to such a regimen. Parenterally administered thiamine injections, together with thyroid extract, may have aided in the patient's rapid recovery. Although the heart is clinically and electrocardiographically normal at present, a teleroentgenogram demonstrates persistent enlargement of the pulmonary conus. This sequel has occurred in other cases.

EXFOLIATIVE DERMATITIS FOLLOWING INGESTION OF PHENYLBUTAZONE (BUTAZOLIDIN)

Harold C. Fishman, M.D., Beverly Hills, Calif.

and

Josephus Reynolds, M.D., Los Angeles

Phenylbutazone (Butazolidin) is the pyrazole derivative 4-butyl-1,2-diphenyl-3,5-pyrazolidinedione sodium. It is being used extensively in the treatment of rheumatoid arthritis, ankylosing spondylitis, arthritis with psoriasis, degenerative joint disease, acute peritendinitis, and gout. Over 10% of patients have been reported unable to tolerate the drug. Reported toxic manifestations include morbilliform rash, edema, nausea, activation of peptic ulcer, vertigo, stomatitis, insomnia, nervousness, thrombocytopenia, and agranulocytosis. It has been said[1] that a rash occurs in only 3 to 4% of patients, that it "subsides rapidly on discontinuance of medication," and that desensitization with minute doses of phenylbutazone has "made possible continuation of therapy in some of those who show rashes."

As we were unable to find any reference in the literature to exfoliative dermatitis attributable to the drug and as we feel that our case indicates that continued use of the drug may be definitely dangerous and absolutely contraindicated after a rash has been observed, this instance of exfoliative dermatitis following the ingestion of phenylbutazone seems to merit prompt reporting.

REPORT OF A CASE

A 60-year-old white housewife was seen by an orthopedist for treatment of a whiplash injury of the neck sustained in an automobile accident on Oct. 14, 1952. She began to take phenylbutazone on Oct. 17, 1952. She took 4 tablets (200 mg. each) daily and stopped after taking 29 tablets over a period of about one week. The patient noticed a slight rash after she took the 16th tablet but did not notify her physician until she had taken 29 tablets. He advised immediate suspension of the medication and referred her to an internist (J. R.), who first saw her on Nov. 6, 1952.

Examination revealed fever, puffiness of the face, burning sensation on the skin, and a morbilliform rash on the face and trunk, but practically none on the extremities. On Nov. 8, 1952, she felt "hot and puffy," vomited, and had frequent bowel movements. The rash was now generalized, confluent, and morbilliform. Her hands and face were swollen, and her fingers were stiff. Her temperature was 102 F, and she was drowsy. Her appearance suggested a serum sickness type of reaction. Cortisone acetate was prescribed in initial dosage of 200 mg. every 24 hours, and she was also given diphenhydramine (Benadryl) hydrochloride. On Nov. 10, 1952, the skin of the hands and fingers was tight, and the rash had a purplish color. The palms and soles began to itch. Cortisone dosage was increased to 400 mg. per day, but the woman's temperature remained at 102 F. On Nov. 12, 1952, itching continued, but the swelling subsided somewhat. There was generalized lymphadenopathy with considerable enlargement of axillary, epitrochlear, and inguinal lymph nodes. The liver was felt 2 in. (5.08 cm.) below the right costal margin. Therapy with cortisone (100 mg. per day) and diphenhydramine was continued. The rash began to subside, and the patient felt considerably better.

Blood Findings in Woman with Exfoliative Dermatitis Following Ingestion of Phenylbutazone

It is of interest to note that the initial blood studies (Nov. 12, 1952), made when the patient presented a serum sickness type of reaction, revealed a preponderance of monocytic cells. Subsequent blood tests showed a gradual return to normal. At no time was there any evidence of eosinophilia or granulocytopenia. Pertinent blood findings appear in the table. Examination of the bone marrow was made on Nov. 24, 1952, with the following findings: Smears and sections of aspirated sternal bone marrow revealed a normal dispersion of erythroid and myeloid elements. Platelets and megakaryocytes were abundant. No cells foreign to marrow were observed.

A relapse occurred on Nov. 18, 1952. The woman's face again became swollen to twice its normal size. There was a recurrence of the eruption, which was papular and confluent with marked itching. There was no adenopathy, hepatomegaly, or splenomegaly. Inasmuch as the rash was becoming progressively severer and more widespread, a dermatologist (H. C. F.) was consulted on Nov. 24, 1952.

The patient was then treated with fractional x-ray therapy, potassium permanganate 1:5,000 baths, and methapyrilene hydrochloride (Histadyl) orally and intramuscularly. After three weeks of this treatment, the rash was still getting worse. The patient was then admitted to the hospital, and hydrocortisone acetate was administered orally in doses of 40 mg. four times a day. The potassium permanganate baths were continued. Within a few days, the dermatitis began to subside, and slow improvement continued daily and without further exacerbation. The patient was discharged from the hospital on the 27th day feeling better but very weak, with residual generalized erythroderma and swelling of the hands and feet. The dose of hydrocortisone acetate was reduced to 60 mg. daily. At home, the patient was given hydrocortisone acetate for the next four months, and the dosage was gradually reduced. By that time her skin had just returned to normal, but the hair of the scalp remained very sparse.

---

[1] Kuzell, W. C., and Schaffarzick, P. W.: Phenylbutazone (Butazolidin®), Bull. Rheumat. Dis. 3:23 (Nov.) 1952.

When first seen by the dermatologist, after the rash had been present for about two months, the skin showed a diffuse erythema, with mild exfoliation and thickening involving the entire body, but most extensively on the chest, abdomen, anterior upper and lower arms, anterior thighs, and dorsum of the hands and wrists. There were also reddish to purplish, discrete, flat, large papules scattered throughout. After three weeks, at the time of admission to the hospital, the rash had become much worse and showed a very marked exfoliation with considerable thickening, edema, and weeping in many of the crease areas.

After oral administration of hydrocortisone acetate, the exfoliative dermatitis began to clear in a few days and was practically gone in one month. It required four more months for the remaining erythroderma to subside and for the skin to return to normal. A biopsy of the skin from the dorsum of the left hand on Nov. 24, 1952, showed hyperkeratosis, marked edema of the upper cutis, and marked infiltration with small, round cells of the mid-cutis, especially perivascularly.

SUMMARY AND CONCLUSIONS

A case of exfoliative dermatitis following the ingestion of 29 200 mg. tablets of phenylbutazone (Butazolidin) in a 60-year-old white housewife is reported in detail. This patient was acutely ill, and for a while it seemed that she might not live. The total duration of her illness was seven months, from onset to recovery. We believe this is the first such case reported.

It is felt that phenylbutazone is a potentially dangerous drug that should not be prescribed indiscriminately or without close supervision and observation of the patient. Before advising its use, the physician should give very careful consideration to the disability, discomfort, and danger inherent in the disease being treated, in comparison with the possible hazards of the medication. Our experience indicates that, even after cessation of phenylbutazone therapy, a rash can continue to progress and can develop into an almost fatal exfoliative dermatitis. Such an eventuality casts grave doubts on the validity of published statements that the rash subsides rapidly after discontinuance of medication and that it may be safe to continue therapy after desensitization by minute doses.

105 N. San Vicente Blvd. (Dr. Fishman).

Gastrointestinal Disorders and Flying.—It is logical that flying should be interdicted for patients having lesions of the gastrointestinal tract that might perforate under the stress of rapidly expanding gas. This applies to patients with active peptic ulcer. Patients with quiescent ulcers may travel in pressurized aircraft. They should be given carminatives for flatulence, and hyoscine to prevent air sickness. Patients with diverticulosis should not fly. Entrapment of air in a diverticulum is quite painful, and perforation is possible. . . . Diaphragmatic hernia is another contraindication to flying. A patient with a colostomy should stay on the ground. While there he may have perfect control over the colostomy, at higher altitudes expansion of intestinal gases may be attended by disagreeable and embarrassing results.—S. Kreinin, M.D., Which Patients May Fly, *GP (Journal American Academy General Practice)*, August, 1953.

COUNCIL ON FOODS AND NUTRITION

The following article was prepared at the request of the Council on Foods and Nutrition.

James R. Wilson, M.D., *Secretary.*

TRACE ELEMENTS IN BRUCELLOSIS

David T. Berman, D.V.M., Ph.D.
Madison, Wis.

Assertions that trace elements have a prophylactic or therapeutic effect on Brucella infections in man and lower animals have been circulated widely. These claims have been based on uncontrolled observations. The results of a controlled experiment on cattle indicate that the addition of a trace element supplement to a practical dairy ration had neither a prophylactic nor a therapeutic effect on the course of experimentally produced brucellosis. Animals fed the unsupplemented ration and vaccinated with Br. abortus strain 19 were significantly more resistant to the induced infection than the supplement-fed cattle. The control ration apparently furnished adequate amounts of the trace elements, since there were no differences in the concentrations of these elements in the blood or livers of animals fed the basal or supplemented diet. Significant differences were not observed in the concentrations of trace elements in the tissues of animals that resisted the infection as compared with those that had been susceptible. The available evidence does not support the claims advanced for the prophylactic or therapeutic efficacy of trace elements in brucellosis.

Claims that brucellosis is fundamentally a syndrome of trace element deficiency—or that such a deficiency occurs frequently, both in domestic animals and human beings, and is a major factor in the susceptibility of the host to invasion by Brucella—have been circulated widely.[1] These claims apparently stem from a report[2] that spectroscopic analysis of the blood and pituitary glands of cattle with Brucella agglutinins revealed significantly lower concentrations of manganese, copper, and cobalt than those observed in the tissues of normal animals. So-called practical feeding experiments are claimed to have shown that supplementation of the ration of infected cattle with manganese, copper, and cobalt resulted in the loss of specific agglutinins.[3] On the basis of such assertions trace elements claimed to be "Bang's disease cures" have been sold to many livestock owners. Also, trace elements have been said to have therapeutic efficacy in human brucellosis.[4]

Adequate controls were not included in the trials cited in support of the efficacy of trace elements. It should be emphasized that absence of the cardinal sign of abortion from a herd of cattle cannot be construed as evidence of freedom of infection. Studies of the natural course of the disease[5] indicate that infected animals rarely abort more than once after initial exposure but that most remain carriers of the infection. In the normal course of events storms of abortion in infected herds occur only when the population of susceptible animals reaches a sufficient concentration. Between these dramatic episodes infection is maintained in carrier animals, most of which reproduce quite normally. The use of almost any material in a herd of cattle after an abortion storm will appear, to the uncritical observer, to have effected a change in the clinical picture in the herd. A variety of products have been sold to livestock men as therapeutic agents for brucellosis of cattle. The results of controlled experimental studies have shown some of the most widely advertised of these to be without merit.[6] It appears that the reputed success attending their use in the field was attributable to the natural tendency

of the abortion phase of the disease to be self-limiting in individuals and to occur in cycles in herds.

Observations of serologic reversals in cattle, such as those cited above, following the use of supposed therapeutic agents must also be examined critically unless the trials include adequate numbers of control animals not given the material. Spontaneous serologic reversals occur in cattle over varying periods of time after initial exposure. Beach and co-workers[7] found that 14 of 37 seropositive infected cattle in one experimental herd lost their agglutinins over a two year period after the initial exposure. No treatment was employed. Winner[8] has observed an incidence of serologic reversals of about 17% in several thousand animals tested in an official eradication program. Similar spontaneous recoveries, with serologic reversals, have been observed by Spink[9] in 10 of 65 untreated cases of human brucellosis.

The adequacy of the diagnostic criteria employed is a fundamental consideration, which must be made in evaluating the reports of antibrucellar activity of trace elements (or any other chemotherapeutic material) in human beings. This is particularly true in chronic brucellosis.[10] Diagnostic criteria for human brucellosis have been discussed in two recent reviews.[11]

Although evidence has been presented that indicates that the nutritional state of the host may exert a profound effect on its response to a variety of infectious agents, most of these effects are demonstrable only by the use of restricted rations.[12] In a study by Hart and co-workers[13] it was found that "A high plane of nutrition, involving the feeding of alfalfa hay, minerals, cod liver oil and iodized salt had no effect in developing a resistance in cattle to Brucella abortus, as compared with a ration of lower protein content supplemented with common salt but no other minerals." The trace elements were not specifically considered in this study.

Frank states of copper or cobalt deficiencies have been recognized in cattle and sheep under natural conditions in areas where these elements are present in the soil in amounts insufficient to supply the requirements of the animals.[14] Quantitative requirements of manganese for farm animals have been established only in the case of poultry. The needs for swine are certainly much lower than for chicks, but published data on their actual requirements are not in agreement. Although little is known about the requirements of manganese for cattle, its content in the feeds that commonly make up their rations appears to be high enough to meet their probable needs.[14] The occurrence of deficiencies of these trace elements in the normal human diet is highly improbable.[15]

Evidence has not been furnished of increased prevalence of bovine brucellosis in areas where the soil is deficient in trace elements. Nor has the addition of manganese to fertilizer mixtures or to the ration influenced the prevalence of the disease in the manganese deficient areas in Florida. Davis[16] has investigated 30 infected cattle herds in that state. Of these, 27 had been fed manganese as a regular constituent of a mineral mixture and were on farms where manganese was included in the fertilizer applied to pastures. In addition, a brucellosis outbreak occurred at the Everglades Experiment Station among cattle being fed manganese and on pastures heavily fertilized with this element.

A controlled study of the effects of trace elements on bovine brucellosis has been conducted at the University of Wisconsin[17] as a part of a large-scale investigation on this disease.[18] The trial involved 5 experimental groups of approximately 20 cows per group. All groups were maintained throughout the experimental period on a practical dairy ration composed of either mixed legume hay or legume hay with corn silage, together with a grain mixture, with the following composition: Whole oats, 19%; corn or wheat, 48%; bran, 17.5%; soybean oil meal, 15%; and iodized salt, 0.5%. One group of 19 unvaccinated animals received a trace element supplement, one part of which was mixed with 99 parts of the grain mixture. The proportions of the mineral mixture were: Techmangam (product of Tennessee Eastman Corp., containing 65 to 67% $MnSO_4$), 100: $CuSO_4$, 1.0; $CoSO_4$, 1.5; $ZnSO_4$, 0.5; and $MgSO_4$, 3.0. The supplemented grain mixture was fed to the animals of the group during a 4½ month period before experimental exposure to Br. abortus and for a period of 11 to 18 months after that exposure. The levels fed furnished a minimal daily intake of one ounce of the trace element mixture per cow.

The animals in all groups were exposed by instillation of 12×10^6 organisms of a highly pathogenic culture of Br. abortus (strain 2308) into the conjunctival sac. Sixteen of the 19 animals fed trace elements, and 18 of the 22 unvaccinated, unsupplemented control cows were pregnant at the time of exposure. Careful bacteriological and serologic studies were made of all animals. The experimental design permitted comparison of the response to infection between groups of unvaccinated animals with or without supplemental trace elements in the ration and further comparison with the response of vaccinated animals that had not received the trace element supplementation. The results are summarized in table 1.

Response to Brucella of Trace Element-Fed Cattle, Control Cattle, and Unsupplemented Vaccinated Cattle

	Abnormal Parturitions		Normal Parturitions		Nonpregnant			
Group of Cattle	Infected Cattle	Non-infected Cattle	Infected Cattle	Non-infected Cattle	Infected	Non-infected	Sero-positive Animals*	Total Animals per Group
Trace element-fed	12	0	1	3	1	2	17	19
Controls	14	1	3	0	2	2	22	22
Vaccinated before maturity	3	1	0	10	0	0	8	14

* Animals were classified as seropositive if at any time during the postexposure period the agglutinin titer was 1:100 or higher.

Of the 16 pregnant, supplement-fed animals, 12 aborted, as did 15 of the 18 pregnant control cows, and 4 of the 14 vaccinated cows. Br. abortus was isolated from 14 of the 19 trace element-fed cattle, from 19 of the 22 controls, and from 3 of the 14 vaccinated cows. It is clear that there was no difference between the group fed trace elements and the unvaccinated controls in their resistance to induced infection with Br. abortus. On the other hand, vaccinated animals that had not received the trace element supplemented ration were significantly more resistant to the same experimental infection than the animals of either of the unvaccinated groups.

Animals from the various groups were maintained on the test rations for periods of 11 to 18 months after the experimental exposure to determine whether differences in the rate of spontaneous recovery from infection might become apparent. Serum agglutination tests and cultures of the milk were made at regular intervals during this period. Differences were not apparent between the trace element-fed group and the unvaccinated controls in the number of times Br. abortus was isolated from the milk or in the number of serologic reversals.

Analytical studies were also carried out by the Wisconsin group[19] to determine the concentrations of trace elements in the blood and livers of animals in the various experimental groups of animals. Blood samples were obtained before and after the experimental exposure. Liver samples were taken from many of the animals at necropsy following exposure. The authors concluded that the unsupplemented ration supplied abundant amounts of copper, zinc, cobalt, and manganese, since significant differences were not observed in the concentrations of these elements in the blood or livers of animals fed the basal ration or those fed the trace element supplemented diet. It appears that animals that receive adequate supplies of the trace elements are unable to store in the liver additional amounts that might be furnished by dietary supplements. Comparisons also were made of the concentrations of trace elements in the livers of animals that had resisted the infection as compared with those that had been susceptible. Significant differences were not observed.

The results of this controlled study indicate that the supplementation of a practical dairy ration with trace elements, in proportions recommended by the supporters of the efficacy of such products, has neither a prophylactic nor a therapeutic effect on the course of experimentally produced bovine brucellosis. The use of such products cannot be expected to aid in the control of animal brucellosis. Indeed, their use, to the exclusion of proved effective methods of control based on sanitation and vaccination, may result in seriously undermining basic control and eradication programs.

Since cases of human brucellosis occur only as a result of direct or indirect contact with the animal reservoirs of the disease, the problem of control of the infection in human beings depends on control and eradication of the disease in the livestock population. Certainly the results of experiments on the natural host of Br. abortus do not support the claims advanced for the therapeutic efficacy of trace elements in infections of human beings.

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

James R. Wilson, M.D., *Secretary.*

Matchless Brand Dietetic Pack Golden Sweet Corn (Cream Style).

Ingredients: Golden cross variety corn, packed in water without any added sugar or salt.

Analysis (submitted by distributor).—Total solids 22.7%, moisture 77.3%, fat (ether extract) 1.06%, protein (N × 6.25) 2.56%, crude fiber 0.32%, available carbohydrate 17.88%, sodium 3.20 mg./100 gm.

Calories.—0.91 per gram; 26.0 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Matchless Brand Dietetic Pack Whole Kernel Corn.

Ingredients: Tendermost variety corn packed in water without any added sugar or salt.

Analysis (submitted by distributor).—Total solids 17.4%, moisture 82.6%, fat (ether extract) 0.51%, protein (N × 6.25) 2.04%, crude fiber 0.33%, available carbohydrate 13.81%, sodium 1.2 mg./100 gm.

Calories.—0.68 per gram; 19.3 per ounce.

Use.—For use in low sodium and other therapeutic diets.

Matchless Brand Dietetic Pack Sweet Peas.

Ingredients: Peas (surprise variety) packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 11.7%, moisture 88.3%, fat (ether extract) 0.20%, protein (N × 6.25) 3.14%, crude fiber 1.34%, available carbohydrate 5.33%, sodium 8.58 mg./100 gm.

Calories.—0.36 per gram; 10.2 per ounce.

Use.—For use in low sodium and other therapeutic diets.

A STATEMENT CONCERNING VITAMIN D PREPARATIONS REGARDED AS SUITABLE FOR USE IN COUNCIL-ACCEPTED VITAMIN D FORTIFIED MILKS

Concurrent with the increasingly wide use of vitamin D-fortified milk, a number of vitamin D concentrates containing various emulsifying agents have come into use. The safety of some of these emulsifiers does not appear to have been completely established as yet. It is the considered opinion of the Council that such substances should not be incorporated in foods for widespread use until convincing evidence is available demonstrating their harmlessness. Therefore, only those vitamin D concentrates containing emulsifying agents permitted as optional ingredients in standards for foods under the Food, Drug, and Cosmetic Act will be considered as suitable for use in Council-accepted vitamin D milks or other accepted products.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

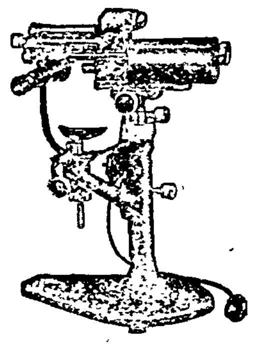
APPARATUS ACCEPTED

The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

Ralph E. De Forest, M.D., *Secretary.*

Rodenstock Eye Refractometer

Optische Werke G. Rodenstock, Munich 5, Germany. Distributor: Anton Heilman, 75 Madison Ave., New York 16.



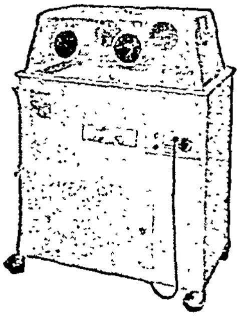
Rodenstock Eye Refractometer

The Rodenstock Eye Refractometer is an instrument for measuring the total refractive power of the eye and determining its astigmatism, including the inclination of axis. Crated for shipment, the instrument measures 49 by 78 by 66 cm. (19 by 21 by 26 in.) and weighs 50 kg. (110 lb.). This shipping weight includes the following accessories: a schematic eye for practice, a transformer for 110 to 220 volt alternating current or a converter for direct current supply, spare bulbs, sanitary shield, shield for the eye not being examined, plastic cover, carrying case, and a wrench for releasing the instrument from the carrying case.

Evidence from sources acceptable to the Council showed that the instrument was sound in principle as a means of measuring ametropias and astigmatism.

Infantair, Model 1500

Continental Hospital Service, Inc., 18636 Detroit Ave., Cleveland (Lakewood) 7, Ohio.



Infantair, Model 1500

The Infantair, Model 1500, is an incubator for infants equipped to supply warmth, humidity, and oxygen. The top, called the Perma-Vue Hood, is a rectangular dome molded out of a single piece of stout transparent plastic substance with two portholes. A nipple is provided for attachment to the supply of oxygen.

The apparatus requires 110 volts of either alternating or direct current and draws 736 watts. It is equipped with casters for rolling on the floor. Unpacked, it measures 123 (height) by 89 by 50 cm. (48½ by 35 by 19½ in.) and weighs 48 kg. (105 lb.). Packed for shipment it weighs 119 kg. (260 lb.) and measures 132 by 94 by 56 cm. (52 by 37 by 22 in.).

Evidence from sources acceptable to the Council indicated that this apparatus is sound in construction and satisfactory in operation.

"EQUALIZATION PAY" FOR PHYSICIANS IN ARMED FORCES

At the annual meeting of the American Medical Association, which was held in New York City in June of this year, certain questions arose concerning the "equalization pay" authorized for physicians who are serving in the armed forces and in the United States Public Health Service. This editorial has been prepared in accordance with the wishes of the House of Delegates and in order to make public background information concerning the bases and justification for such pay.

The authority for this special pay is contained in Section 203 of Public Law 351, 81st Congress, known as the "Career Compensation Act of 1949," as amended by Public Law 410, 82nd Congress, and Public Law 84, 83rd Congress. This act, as amended, provides for the payment of $100 a month to those officers commissioned in the Medical, Dental, and Veterinary Corps of the regular service and ordered into the active military service prior to July 1, 1955, and to those reserve officers who volunteer for, or are ordered into the active military service prior to July 1, 1955, for a period of one year or longer.

After the close of World War II, the armed forces experienced difficulties in the procurement of physicians. Many members of the peacetime corps were eligible for retirement; many others resigned to obtain civilian positions. At the same time the procurement of new officers became increasingly difficult. This situation would have caused much concern even if our military forces had followed the traditional pattern and rapidly reverted to small peacetime forces. Instead, world conditions subsequent to World War II required that we maintain large forces and global garrisons. As a result, the medical services were not able to maintain, on a voluntary basis, a Medical Corps competent to furnish even a minimal standard of medical attendance to the armed forces.

The Congress, in 1947, explored ways and means of meeting this critical situation. Investigation into the causes of the shortage of medical officers revealed that physicians had to be willing to accept a considerable financial sacrifice if they chose to accept a military career. It would, of course, have been impractical to attempt to eliminate entirely the disparity of income between the civilian physician and the medical officer. However, during the course of the hearings on this plan, it became evident that, entirely apart from this difference in earnings, a basic inequity existed in the pay structure of the armed forces. As a result, Congress selected a reimbursement plan to create, insofar as possible, equality of compensation between the medical officer and the other officers of the armed forces. Such a plan, it appeared, would be equitable and economical, yet provide a necessary vehicle for the procurement and retention of career medical officers.

The question of equality of compensation requires some clarification. Although the American Medical Association has not made a comparative study of the incomes of physicians in service and in civilian life, nor of the incomes of officers in the various branches of the armed services, the figures compiled by the Office of the Surgeon General of the Army appear to be valid. The study of the Surgeon General reveals that a person pursuing a four year technical or scientific course leading to a baccalaureate degree in an accredited university meets, upon graduation, the educational requirements for appointment as an officer. In contrast, a medical student must finance a total college and professional education of up to eight years. Internship requires an additional year of training. His former classmates who have entered the military service in the meantime have been receiving full pay and allowances as officers. When the physician finally meets the requirements for a commission in the armed forces, his former classmates have a four to five year lead. Thirty years after they have started their respective careers, these categories of officers are approximately $81,000 ahead of the medical officer, even though the medical officers are originally commissioned one grade higher. It was on this clearly justifiable basis and in the belief that it would prove to be at least a partial solution to the problem that Congress provided for the equalization pay. All the reasons advanced in the interest of the passage of such legislation at that time have equal if not increased validity today.

As a result of the "emergency," which has existed for the past several years, physicians have been provided from reserve components and directly from civilian life by means of the "Doctor-Draft" law. Many of these physicians are mature and experienced and occupy responsible positions; such officers are now being released from the active military service to return to their civilian practices. To maintain the stability and efficiency of the Medical Corps a percentage of these officers should be replaced by career officers. Thus, the maintenance of an equalization pay is essential if even a minimum number of career officers is to be recruited from this potential source.

It is significant that the payment of this special pay should have had a marked effect upon military procurement programs. Inasmuch as it certainly does not equalize the pay scale of the medical officer and the other officers of the armed forces, it is clear that its effectiveness lies elsewhere. It promises, in effect, fairness of treatment and careful consideration in the advancement toward professional skill, the same consideration evidenced by taking into account the additional years of training that a physician must undergo.

The terms "bonus" or "incentive pay" as applied to additional compensation for doctors are misleading.

These terms make it appear that members of the health professions are being singled out for special treatment not accorded to members of other corps or branches of the service. This was not the intention or the result of the law, which was enacted primarily upon the recommendation of the Department of Defense. The real purpose of the law was to make the pay of physicians in uniform more closely approximate comparative earnings for similar personnel outside of the service and to adjust, in terms of total compensation received during a service career, the amount received by members of the health professions with those received by other career officers.

SERVING THE PUBLIC

There probably are few persons in the United States today who have not heard the words "*public relations*." How many have offered their opinion on how to achieve effective relations is not subject to count, but some who are trained in this field in exasperation have said almost everyone at some time has had some advice to offer. The subject has been of particular concern to the medical profession during the last few years. As a result there have been formed many committees and departments within the associations' framework to deal specifically with public relations. Much has been accomplished by those who have been sufficiently farsighted to see the difference between publicity and public relations. Some of the state medical societies and county medical societies have originated ideas for their members and for the public that have done much to increase and even reestablish in some instances the bond between doctors and patients.

Recently there came to the attention of the editorial department of The Journal a statement placed in a local newspaper by the Los Angeles County Medical Association. This local society offered to the public first aid instructions to meet most household emergencies. The reader can paste the statement, cut from the newspaper, on the back of a medicine cabinet door or in any other equally handy location. Its health value in the household is obvious, and its public relations value should be equally obvious.

In the same mail for The Journal office there was a booklet entitled "Information for Patients" prepared by the Presbyterian Hospital in Philadelphia. Written in a spritely but fully informative way, it tells the patient what he should know before he arrives at and after he enters the hospital. It freely discusses services and costs and even offers a reply to the question "Are hospital charges high?" The booklet is pocket-sized and contains about 50 pages of information on subjects from insurance to birth certificates and even meals for guests. Many frequently heard questions are answered, and the booklet will do much to put the patient, his family, and his guests at ease.

These are examples of the acts of persons genuinely interested in providing health service for the community. Nothing but good can come of such activities, and they, like similar efforts, can be emulated in other centers to the advantage of all.

A JOB WELL DONE

On page 665 of this issue there is published in full the report of Mr. Eugene R. Warren, Special Assistant Attorney General of the State of Arkansas. Mr. Warren has taken several months from his law practice to gather evidence to establish that an eclectic medical license issued years ago to Jacob S. Schirmer was obtained by fraud and deceit. Mr. Warren is to be congratulated for his painstaking thoroughness in assembling documentary proof that Schirmer not only was practicing medicine in Arkansas illegally but was an exponent of unestablished and discredited forms of therapy for which he charged suffering victims of chronic disease large sums of money payable in advance.

Mr. Warren's task was perhaps made easier by reason of the fact that certain departments at the headquarters of the American Medical Association were able to furnish him documentary proof of some of the aspects of the fraud practiced on the citizens of Arkansas from the licensure standpoint and on many others suffering from disease, or believing that they were so afflicted, who had gone to the so-called research hospital. Patients the country over have been urged by certain alleged ministers of the gospel to go to Schirmer for treatment. While it is probably true that the details of his fraudulent character may not have been known to them, nonetheless they found a person outside the pale of organized medicine whose organizational abilities suited their needs in exploiting worthless drugs that they were selling or promoting. Specifically referred to in this instance is Gerald Winrod, an evangelist, radio orator, and publisher, who has written frequently in his "Defender Magazine," praising several widely known cancer quacks, the uselessness of whose medicines and treatments is well known to the medical profession. By "defending" these persons, Mr. Winrod has effectively classified them, as far as the true nature of their activities is concerned.

Also referred to is the Christian Medical Research League of Detroit, in which Mr. Winrod seemed to have much interest and that sells "Glyoxylide" at $25 for 2 cc. ampules. These ampules contain material that has been described by chemists of the federal government as being indistinguishable from distilled water. The preparation has recently been the subject of an order by the Federal Trade Commission directed against Dr. William F. Koch and others, forbidding them to advertise this and their other nostrums as having any therapeutic merit in any of the disease conditions for which they are sold.

If the matter reported on is the subject of testimony in the circuit court of Clay County, Ark., it is entirely possible that further details of this sordid combination will be brought to light. Exploiting human misery is a ghoulish business. To reveal the true nature of those who follow this course of conduct is indeed a service not only to those in Arkansas but to the nation as a whole. It is for this reason that the full report of the investigation is printed. Public and licensing officials elsewhere should be alert to the possibility that similar persons operate in their jurisdictions.

MEDICAL NEWS

CALIFORNIA

Meeting on Cerebral Palsy.—At the meeting of the Cerebral Palsy Association, Oct. 21, 3-5 p. m., at the Los Angeles County Medical Association, 1925 Wilshire Blvd., Dr. Brevin Plum, professor of pediatrics, Royal Hospital Medical School, Copenhagen, Denmark, will present "Early Diagnosis and Treatment of Cerebral Palsy."

Personal.—Dr. Francis Scott Smyth, dean, University of California School of Medicine, San Francisco, has been appointed by President Eisenhower to the board of foreign scholarships for a term of three years. The board is concerned with the management of the Fulbright Fellowship program of the Department of State.

Symposium on Cardiac Disease.—The Los Angeles County Heart Association holds its annual symposium on cardiac disease, Oct. 20-21, at the Wilshire Ebell Theatre, Los Angeles. Dr. Edgar F. Mauer, president of the Los Angeles County Heart Association, will open the meeting at 9:30 a. m. Guest speakers will be Drs. George E. Burch, New Orleans, Lewis Dexter, Boston, Harald M. Eliasch, Stockholm, Sweden, and Paul Wood, London, England. In addition to the presentation of papers, they will participate in a round-table discussion during the Tuesday afternoon symposium on the surgical relief of mitral stenosis, when, together with Dr. George C. Griffith, Pasadena, they will discuss valvulotomy for mitral stenosis, selection of patients, role of cardiac catheterization, and preoperative and postoperative care and results. Dr. William Paul Thompson, Los Angeles, will serve as moderator.

CONNECTICUT

Hospital Lectures.—The Hartford Hospital announces the following lectures in its Saturday morning 11 o'clock series:

Oct. 17, Lewis W. Hill, Boston, Oral Cortisone in Asthma and Eczema in Children.
Oct. 24, John F. Enders, Ph.D., Boston, Some Recent Advances in Poliomyelitis (Dwight Griswold Memorial Lecture).
Oct. 31, William Dameshek, Boston, Idiopathic Thrombocytopenic Purpura.

FLORIDA

State Medical Election.—The Florida Medical Association at its annual meeting in Hollywood installed Dr. Frederick K. Herpel, West Palm Beach, as president; elected Dr. Duncan T. McEwan, Orlando, president-elect, and Drs. Thomas H. Bates, Lake City, Russell B. Carson, Fort Lauderdale, and Thomas C. Kenaston, Cocoa, vice-presidents; and reelected Dr. Samuel M. Day, secretary-treasurer, and Dr. Shaler A. Richardson, editor of the journal, both of Jacksonville.

District Medical Meetings.—The Northwest Medical District of the Florida Medical Association will meet at the W. T. Edwards Tuberculosis Hospital, Tallahassee, Oct. 19. The address of welcome by Dr. Charles F. James Jr., Tallahassee, president, Leon-Gadsden-Liberty-Wakulla-Jefferson County Medical Society, will open the scientific assembly at 2:30 p. m. By invitation Dr. Francisco A. Hernandez, Miami, will present "The Clinical Differentiation of Congenital Heart Lesions Amenable to Surgery," and Dr. Milton S. Saslaw, Miami, "Paradoxical Skin Response in Rheumatic Activity: A Possible Test." Refreshments by the host society will precede dinner, 6:30 p. m., ($5).

The Northeast Medical District will meet at the Ponce de Leon Golf Club in St. Augustine, Oct. 20. The scientific assembly will open at 2:30 p. m. with an address of welcome by Dr. John M. Canakaris, Bunnell, president, St. Johns County Medical Society. Dr. C. Ashley Bird, Jacksonville, will discuss "Diagnosis and Treatment of Intracranial Aneurysms," and Dr. Francisco A. Hernandez, Miami, will discuss, by invitation, "The Clinical Differentiation of Congenital Heart Lesions Amenable to Surgery."

The Southwest Medical District will have its meeting in the Palm Room, Tampa Terrace Hotel in Tampa, Oct. 21. The address of welcome by Dr. Arthur R. Knauf, Tampa, president, Hillsborough County Medical Society, will precede the presentation by Dr. Edward I. Melich, Bay Pines, of "Digitalis Brought Up to Date." By invitation Dr. Milton S. Saslaw, Miami, will discuss "Paradoxical Skin Response in Rheumatic Activity: A Possible Test."

The meeting of the Southeast Medical District, scheduled for the Flotilla Club, West Palm Beach, Oct. 22, will open with an address of welcome by Dr. Graham W. King Jr., Delray Beach, president, Palm Beach County Medical Society, 2:30 p. m. "The Fundamentals of Fluid and Electrolyte Balance (Explanation of Milliequivalents)" will be discussed by Dr. George F. Schmitt Jr., Miami, and "The Treatment of Injuries of the Face and Head" by Dr. George W. Robertson III, Miami. Refreshments by the host society will precede dinner at 6:30 p. m. ($5).

ILLINOIS

Clinics for Crippled Children.—The University of Illinois division of services for crippled children is conducting clinics providing diagnostic orthopedic, pediatric, speech, and hearing examinations together with medical, social, and nursing services. There will be special clinics for children with rheumatic fever and for cerebral palsied children. Clinics are held by the division in cooperation with local medical and health organizations. Clinicians are selected among private physicians who are certified board members. Any private physician may refer or bring to a convenient clinic any child for whom he may want examination or consultative services. The following clinics have been scheduled:

Oct. 21, Chicago Heights, St. James Hospital.
Oct. 22, Bloomington, St. Joseph's Hospital; Mt. Vernon, Masonic Temple; Rockford, St. Anthony Hospital.
Oct. 23, Chicago Heights (Rheumatic Fever), St. James Hospital.
Oct. 27, Effingham (Rheumatic Fever), Douglas Township Building; East St. Louis, Christian Welfare Hospital; Peoria, St. Francis Hospital.
Oct. 28, Springfield (Cerebral Palsy), Memorial Hospital; Alton, Alton Memorial Hospital.

In carrying on its program the division works cooperatively with local medical societies, hospitals, the Illinois Children's Hospital-School, Chicago, civic and fraternal clubs, visiting nurse associations, local social and welfare agencies, local chapters of the National Foundation for Infantile Paralysis, and other interested groups. The work of the division is intended to extend and supplement—not supplant—activities of other agencies, public or private, state or local, carried on in behalf of crippled children.

Chicago

Lectures on Medical History.—The Chicago Medical School, 710 S. Wolcott Ave., announces that the following lectures in its series, "Introduction to the History of Medicine," will be given in Amphitheater A at 12:30 p. m.:

Oct. 20, Ancient Medicine, Erwin H. Ackerknecht, professor of the history of medicine, University of Wisconsin Medical School, Madison.
Oct. 27, Greek Medicine, Frederick Stenn, lecturer, history of medicine, University of Illinois College of Medicine.

Annual Lectures on Cancer.—The fourth annual cancer lecture series at Northwestern University Medical School is offered at Thorne Hall, Chicago Ave. and Lake Shore Dr., at 5 p. m. on Wednesdays. On Oct. 14, Dr. Algernon B.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Reese, professor of ophthalmology, Columbia University College of Physicians and Surgeons, New York, will discuss ocular neoplasms. Future lectures include:

Oct. 21, Enzyme Levels in the Tumor-Bearing Host, Jesse P. Greenstein, Ph.D., Bethesda, Md.
Oct. 28, Pathologic Diagnosis of Breast Cancer, Otto Saphir, Chicago.
Nov. 4, Carcinoma of the Pancreatoduodenal Area, Richard B. Cattell, Boston.
Nov. 11, Radiation in Tumor Growth, Austin M. Brues, Chicago.
Nov. 18, Carcinoma of the Thyroid Gland, Warren H. Cole, Chicago.
Nov. 23, Clinicopathologic Correlation of Nevi and Malignant Melanomas, Arthur C. Allen, New York.

Meetings for Parents of Preschool Deaf Children.—The Speech and Hearing Rehabilitation Clinic, Illinois Eye and Ear Infirmary, 904 W. Adams St., is sponsoring meetings designed to help parents understand their preschool deaf children and provide preparatory informal training at home until school age is reached. The following lectures will be held at 7:15 p. m.:

Getting Ready to Listen, Oct. 20.
How Your Child Grows, Part I, Oct. 27; Part II, Nov. 3; Part III, Nov. 10.
Experiences in a Nursery School, Nov. 17.
Language and the Pre-Readiness Period, Nov. 24; Dec. 1.
The State and Local Community, Your Child and You, Dec. 8.
Round-Up, Dec. 15.

Demonstrations with children will be held at 10 a. m.: Oct. 26, "Listening," Nov. 30 and Dec. 7, "Lip Reading, Talking, Reading and Writing."

KENTUCKY

Conference on Handicapped Children.—The Kentucky Conference on Handicapped Children will be held at the Seelbach Hotel, Louisville, Oct. 22-23, under the sponsorship of the recently formed Kentucky Coordinating Council for the Study of Handicapped Children and the Nemours Foundation, Wilmington, Del. Dr. Alfred R. Shands Jr., Wilmington, Del., medical director of the foundation, will serve as general adviser to the conference.

University News.—The University of Louisville School of Medicine announces the following appointments: Dr. Earl F. Hoerner, acting chairman of the department of physical medicine and rehabilitation, and acting director of the Rehabilitation Center; Dr. Donald A. Covalt, clinical director of the Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, as consultant to the department of physical medicine and rehabilitation, and to the Rehabilitation Center; and Dr. Hugh B. Lynn, Newark, N. J., as assistant professor of surgery.

MAINE

Legislative Research Hearings.—The Legislative Research Committee of the State of Maine will hold a public hearing Oct. 20, 1:30 p. m., at the state house, Augusta, on the problem of hospital aid, including costs of operation and methods of financial support. The committee will also hold a public hearing Oct. 21, 9:30 a. m., at the state house, on the problem of the organization of public health services.

Mental Health Clinics.—The division of mental health, state department of health and welfare, offers psychiatric clinic service to children and adults in the following cities:

Portland, health and welfare department, 178 Middle St., every Tuesday.
Lewiston, outpatient department, Central Maine General Hospital, every Monday.
Augusta, bureau of health, division of mental health, by appointment.
Waterville, Mansfield Clinic, Thayer Hospital, 3rd Wednesday.
Bangor, outpatient department, Eastern Maine General Hospital, 1st Wednesday afternoon; Valentine School, Union St., 1st Thursday.

A traveling clinic visits the following towns and cities at irregular intervals: Caribou, Houlton, Lincoln, Machias, Rockland, and Rumford. Patients are seen by appointment only. Each child must be accompanied by a parent or guardian. Applications should be sent to the Director, Division of Mental Health, Department of Health and Welfare, State House, Augusta.

MARYLAND

Personal.—At the recent commencement at Washburn University, Topeka, Kan., the alumni association presented a distinguished service award to Dr. Henry R. O'Brien of the U. S. Public Health Service. Dr. O'Brien is a member of the Connecticut State Medical Society. The university conferred on Stacy R. Guild, Ph.D., associate professor of otolaryngology, Johns Hopkins University School of Medicine, Baltimore, the honorary degree of doctor of science.

General Practitioners Meet in Baltimore.—The annual scientific assembly of the Maryland Academy of General Practice will be held at the Lord Baltimore Hotel, Baltimore, Oct. 21. The morning session will be devoted to presentation of "Late Complications of Diabetes: Prevention and Treatment" by Dr. Alexander Marble, Boston, and "The Management of Cardiac Failure" by Dr. Charles C. Wolferth, Philadelphia. Discussion of "The Indications for Pulmonary Resection" by Dr. Herbert C. Maier, New York, 1:15 p. m., will be followed by the speech, "The Management of Osteoporosis," by Dr. Ephraim Shorr, New York. Dr. Robert H. Barter, associate professor of obstetrics and gynecology, George Washington University School of Medicine, Washington, D. C., will present "X-Ray Diagnosis of Pregnancy," 3:45 p. m., and Dr. Charles F. Geschickter, professor of pathology, Georgetown University School of Medicine, Washington, D. C., will discuss "The Newer Treatment of Asthma," 4:45 p. m. The principal address at the banquet will be given by Alfred P. Haake, Ph.D., economic consultant to the General Motors Corporation, whose subject will be "Pills and People." There is no registration fee for the scientific program. Tickets for the banquet ($7.50 per plate for physicians and $5 for their wives) may be obtained from Dr. Nathan E. Needle, 4215 Park Heights Ave., Baltimore 15.

MICHIGAN

Cancer Conference.—The fifth Michigan Cancer Conference will be held at the Kellogg Center, East Lansing, Oct. 21, under the cosponsorship of the Michigan State Medical Society, the two Michigan divisions of the American Cancer Society, and the Michigan Department of Health. The conference theme, "Behind the Scenes in Cancer Control," will be developed by Drs. John S. DeTar, Milan; Solomon G. Meyers, Detroit; Russell L. Mustard, Battle Creek; and James C. Cook, Detroit. Dr. John R. Heller, director of the National Cancer Institute, Bethesda, Md., will report on recent research problems in the cancer field. A five year report on the Hillsdale plan for tumor detection will be given by Dr. Arthur W. Strom, Hillsdale. After luncheon there will be a panel discussion on the morning topics and other questions that the audience may propose. The conference is open to all.

Television Course for Parents.—The University of Michigan Medical School, Ann Arbor, is presenting a course to parents, entitled "The Growing Baby." This telecourse will be carried over television stations WWJ-TV, Detroit, WJIM-TV, Lansing, and WKZO-TV, Kalamazoo, in simultaneous broadcasts. There will be eight consecutive programs, beginning Oct. 18, each Sunday at 1 p. m., originating in the studios of WWJ-TV. The aim of this series is to acquaint parents and prospective parents with the normal physiological processes and growth of their children and with the dangers that may befall their children from birth to about 5 years. "The Growing Baby" is being coordinated by Dr. Harry A. Towsley, associate professor of pediatrics and communicable diseases. The following subjects will be discussed in October:

Lesson 1, Oct. 18, Care of the Newborn, Bruce D. Graham, assistant professor of pediatrics and communicable diseases, and Miss Ruth Carney, RN, assistant professor of nursing.
Lesson 2, Oct. 25, Feeding Your Baby, James L. Wilson, professor of pediatrics and communicable diseases.

Symposium on Virus Infections.—The International Symposium on the Dynamics of Virus Infections will be held at Henry Ford Hospital, Detroit, Oct. 21-23. The Wednesday morning session on mechanisms of virus and rickettsial infections will be moderated by Dr. Thomas M. Rivers, Hospital of the Rockefeller Institute for Medical Research, New York, and the afternoon session on the same topic by Dr. John G. Kidd, Cornell University Medical College, New York. Thursday morning Dr. Albert B. Sabin, the Children's Hospital Research Foundation, department of pediatrics, University of Cincinnati College of Medicine, will be moderator for a discussion on ecology and pathogenesis, and Thursday afternoon Dr. John Paul, Yale University School of Medicine, New Haven, Conn., will moderate a discussion on mechanisms of immunity. "Methods of Virus and Rickettsial Diagnosis" is the topic for the Friday morning session, which will have as moderator Dr. Andrew J. Rhodes, Hospital for Sick Children, Toronto, Canada. Dr. Gilbert J. Dalldorf, division of laboratories and research, New York State Department of Health, Albany, will moderate the closing session Friday afternoon, for which the topic is "Chemical Approaches to Prophylaxis and Therapy of Virus and Rickettsial Diseases."

Institute of Industrial Health.—The Institute of Industrial Health and the School of Public Health, University of Michigan, Ann Arbor, offer a conference on expert and technical testimony in medical and health problems, Oct. 21, at the School of Public Health, 109 S. Observatory St. Dr. Otto Tod Mallery Jr. is director of the institute, and Henry F. Vaughan, Dr.P.H., is dean of the school. The program will include the following presentations:

Attorneys, Technical Witnesses, and the Courts (the conference keynote address), J. Joseph Herbert, LL.B., Manistique.
The Physician's Obligations to the Courts (the medical keynote address), Edward D. Spalding, Detroit.
Judicial Procedure as It Applies to Technical Witnesses, Charles W. Joiner, J.D., Ann Arbor.
Preparation of the Technical Witness Prior to Court Appearance (the attorney's viewpoint), Mr. T. Donald Wade, Detroit.
Medical Preparation of a Medical-Legal Case (the physician's viewpoint), Theodore J. Curphey, Hempstead, N. Y.
Use of Scientific Records and Exhibits in the Court Room, Eli Sherman Jones, Hammond, Ind.
The Dilemma of Official Agencies as to Court Appearance, Mr. William G. Frederick, Detroit.

Dinner at 6 p. m. in the Michigan Union will precede presentation of "Good and Bad Technical Witnesses Based Upon a Compensation Claim in a Simulated Case of Silicosis—A Demonstration," which will be given by a cast of characters including a judge, plaintiff attorney, defense attorney, a court stenographer, good witness, and bad witness. Commentary will be offered by Charles W. Joiner, J.D.

MINNESOTA

Judd-Plummer Memorial Lecture.—Dr. Louis H. Bauer, Hempstead, N. Y., immediate Past President of the American Medical Association, gave the sixth Judd-Plummer Memorial lecture in Rochester, Oct. 2, at St. Mary's Auditorium. His subject was "The Impact of Current Socio-Economic Trends Upon American Medicine."

NEW YORK

Foreign Professors Join State University Staff.—Visiting professors from Brussels, Belgium, Dublin, Ireland, and Birmingham, England, have been appointed to the staff of the State University of New York College of Medicine at Brooklyn for the 1953-1954 academic year. Dr. François Kleyntjens, acting chief, department of neurology, Brussels University Hospital, will serve as visiting professor of physiology. Dr. Edward Solomons, obstetrician and gynecologist of Dr. Steevens Hospital in Dublin, is the guest jointly of the college's department of obstetrics and gynecology and of Maimonides Hospital, Brooklyn, for the month of October. Dr. Solomons is an examiner for membership in the Royal College of Physicians of Ireland. Dr. Brian MacMahon of Birmingham, England, who has spent the past year at the Harvard School of Public Health in the department of epidemiology as a Rockefeller Foundation fellow, has joined the staff of the college's department of environmental medicine and community health, as visiting lecturer.

New York City

Tumor Clinic Conference.—Dr. Harold W. Dargeon, attending pediatrician, Memorial Center for Cancer and Allied Diseases, will be guest speaker at a tumor clinic conference at Harlem Hospital, Oct. 21, 10:45 a. m. His subject will be "Diagnosis of Pediatric Cancer."

Dr. Crohn Honored.—The American Gastroenterological Association has presented to Dr. Burrill B. Crohn the Julius Friedenwald Medal. Dr. Crohn has been affiliated with Mount Sinai Hospital since 1908 and was chief of its gastroenterology clinic from 1924 until 1932, and since that time he has been consultant gastroenterologist. The presentation was made by Dr. Walter C. Alvarez, Chicago.

Lecture on Breast Cancer.—The department of radiology of the New York University College of Medicine will sponsor a lecture, entitled "The Rationale and Results of Simple Mastectomy Plus Irradiation in Treating Breast Cancer," by Dr. Robert McWhirter, professor of radiation therapy, University of Edinburgh, Edinburgh, Scotland, Oct. 22, 8:30 p. m., in the main lecture hall of the university (477 First Ave., near 28th St.).

NORTH CAROLINA

Society News.—The North Carolina Orthopedic Association has elected Dr. Julien E. Jacobs, Charlotte, president; Dr. Everett I. Bugg, Durham, vice-president; and Dr. George W. Holmes, Winston-Salem, secretary-treasurer.

Triennial Alumni Reunion.—The medical and nurses' alumni of Duke University, Durham, will hold their fourth triennial reunion Oct. 22-24. The program will include a scientific session with papers by alumni, special conferences, and departmental open houses. Entertainment will include the Duke-North Carolina State football game, Oct. 24, in Duke Stadium. Dr. Joseph B. Stevens, Greensboro, is president of the Duke Medical Alumni Association, and Arlene Ledford, Durham, is president of the Duke Nurses' Alumnae Association.

OHIO

Society News.—The Cincinnati Otolaryngologic Society has elected Dr. Gerson Lowenthal, president; and Dr. Edward T. Juler, secretary-treasurer. —— The Academy of Medicine of Cincinnati will have as guest speaker Oct. 20, Dr. Frederic A. Gibbs, chief, division of electroencephalography, University of Illinois College of Medicine, Chicago, who will present "Electroencephalography—A Clinical Tool."

Cardiac Poster Contest.—The Cleveland poster art contest sponsored annually in Cleveland schools by the Central Outdoor Advertising Company, is cosponsored this year by the Cleveland Area Heart Society. The subject of the contest is "The Heart and Heart Disease." There will be $600 in awards contributed by J. A. Zimmer. An exhibition will be held in April, 1954, when the prizes will be awarded.

OKLAHOMA

School Health Conference.—Sponsored by the Oklahoma School Health Administrators' Association, Oklahoma Advisory Health Council, Oklahoma State Health Department, and the Oklahoma State Medical Association School Health Committee, the third annual school health conference is being held in Norman, Oct. 16-17. The conference will give attending physicians an opportunity to assist in the planning and development of school health programs. The meeting is scheduled for the week end of the Oklahoma-Kansas football game in Norman, Oct. 17, which is also "Dad's Day" at the university.

TEXAS

Seminars on Social Psychiatry.—The department of psychiatry of the University of Texas Medical Branch, Galveston, announces a special seminar, "The History of Social Psychiatry," to be held each Tuesday at 4 p. m. during the academic year. The seminar group will study psychological factors that contribute to psychiatric disorders.

University News.—Among recent appointments at the University of Texas Medical Branch, Galveston, are those of Dr. Kenneth M. Earle, formerly associated with Dr. Wilder G. Penfield at the Neurological Institute of McGill University, Montreal, who becomes associate professor of neuropathology, and Dr. Truman G. Blocker Jr., professor of surgery at Galveston, who has accepted appointment as dean of the faculty of medicine. Donald Duncan, Ph.D., professor of anatomy, has been appointed associate dean of the Graduate School of the university for the Medical Branch.——Dr. Hans Selye of the University of Montreal Faculty of Medicine, will be a guest speaker on the adaptation reaction, at the medical branch in Galveston, Oct. 22, under the auspices of Phi Delta Epsilon medical fraternity.

VIRGINIA

Bequest to Establish Chair of Surgery.—The late Dr. Stephen H. Watts, from 1907 until his retirement in 1928 professor of surgery, University of Virginia School of Medicine, Charlottesville, bequeathed a half-million dollars to the medical school for the establishment of the Stephen H. Watts Chair of Surgery, any remaining income to be used for research in medicine and surgery.

State Medical Meeting in Roanoke.—The Medical Society of Virginia will meet at the Hotel Roanoke in Roanoke Oct. 18-21, under the presidency of Dr. James L. Hamner, Mannboro. At 11:25 a. m. "The Virginia State Health Department's Legislative Program for Irradication of Tuberculosis" will be presented by Drs. Mack I. Shanholtz, Richmond, commissioner, and William F. Wagner, director, Division of TB Control, Virginia State Department of Health. Monday afternoon Dr. Alexander McCausland, Roanoke, will serve as chairman for a symposium on diagnosis of arthritis and related disorders. Dr. Arnold J. Rawson, Norfolk, will be chairman for a symposium on electrolytes sponsored by the Virginia Society for Pathology and Laboratory Medicine. Dr. Hamner will give the presidential address at 8:30 p. m. Monday. Tuesday morning there will be a cardiology symposium, with Dr. William B. Porter, Richmond, as chairman. Dr. Robert L. King, Seattle, president of the American Heart Association, guest speaker, will discuss "Rheumatic Fever and Heart Disease" at 11 a. m. Panel discussion on cardiac problems will follow. The obstetrical and gynecological symposium Tuesday morning will have as chairman Dr. John R. Kight, Norfolk, and as guest speaker Dr. Charles Hampton Mauzy Jr., professor of obstetrics and gynecology, Bowman Gray School of Medicine, Winston-Salem, N. C., whose topic will be "Obstetrics Now and Twenty-Five Years Ago." A panel discussion will follow his presentation. Tuesday afternoon Dr. Charles S. Wise, professor of physical medicine and rehabilitation, George Washington University School of Medicine, Washington, D. C., will open a symposium with a discussion of the rehabilitation problem. Dr. A. Ray Dawson, Richmond, will moderate a panel discussion on general problems of rehabilitation. Guest speaker in the Tuesday afternoon symposium on lymphomas and leukemias (Dr. Byrd S. Leavell, Charlottesville, chairman) will be Dr. Claude E. Forkner, New York, whose presentation "Advances in Leukemia" will follow a panel discussion on treatment of lymphoma. A cocktail party will precede the banquet, 7 p. m., at which Dr. Vincent W. Archer, Charlottesville, will be installed as president. Wednesday, 9:50 a. m., Dr. Edwin E. Barksdale, Washington, D. C., and associates will present, illustrated with lantern slides, "Some Skin Manifestations of Internal Disorders." A clinical pathological conference will be moderated by Dr. Kinloch Nelson, Richmond, at 11 a. m.

WISCONSIN

State Society to Build New Headquarters.—The council of the State Medical Society of Wisconsin has approved proposals for a building project to house the society's general offices and related activities, now inadequately quartered at 704 E. Gorham St., Madison. The new building will be constructed on society-owned property on the south shore of Lake Monona; the present offices are located on Lake Mendota. Total cost of the new structure is estimated at $415,000.

Pharmacists Institute.—When the Wisconsin Pharmacists Institute meets at the University of Wisconsin, Oct. 22-24, to examine the role of the pharmacist in relation to self-medication and public health, Dr. John E. Steinhaus, University of Wisconsin Medical School, Madison, will speak on antipyretics and analgesics; Dr. Paul G. LaBissoniere, director, Student Health Clinic, Marquette University, Milwaukee, will discuss antacids and laxatives; and Dr. Robert C. Parkin, coordinator of University of Wisconsin graduate medical education, will have as his topic "Self-Medication and Public Health." Papers will be presented on pharmaceutical drug control; miseducation of the public about drugs; oral antiseptic and antibacterial preparations; dental caries; and pharmaceutical legislation. Information may be obtained from Mr. William S. Apple, 301 Chemistry Building, University of Wisconsin, Madison 6.

GENERAL

Fellowship in Gastroenterology.—The American Gastroenterological Association is offering a fellowship for 1954-1955 to a qualified physician in the younger age group to conduct investigative work in gastroenterology. If the physician is unmarried, the stipend is $3,000; if married, $3,600. Applications, which should be returned by Nov. 1, may be obtained by communication with the secretary, Dr. H. Marvin Pollard, University Hospital, Ann Arbor, Mich.

Education of Cerebral Palsied Children.—A "Digest of State Legislation for the Education of Mentally Retarded Children," as it pertains to the cerebral palsied, published by the United Cerebral Palsy Legislative Bureau, is available from the national office (50 W. 37th St., New York 19). Among other essential information, the digest includes a summary of state laws on this subject, as well as a chart of the definitions of mental retardation used in the various states.

Predoctoral Fellowships.—The Life Insurance Medical Research Fund invites faculty members to nominate candidates for 1954-1955 predoctoral fellowships for research in the medical sciences, preferably in the cardiovascular field. Nomination deadline is Nov. 30. The fellowships are open to those who will have completed a year or more of work in a medical or graduate school and can devote most of their time to research; stipends, $2,000-$2,400. Information is obtainable from Dr. Francis R. Dieuaide, scientific director of the fund, 345 E. 46th St., New York 17.

Mental Hospital Institute.—Dr. Kenneth E. Appel, Philadelphia, president of the American Psychiatric Association, has announced that the fifth Mental Hospital Institute will convene at the Hotel Marion, Little Rock, Ark., Oct. 19-22, under the auspices of the American Psychiatric Association Mental Hospital Service. Dr. Winfred Overholser, Washington, D. C., is chief consultant of the service, and Dr. Daniel Blain, Washington, D. C., is director. Dr. Cleve C. Odom, superintendent of the state hospital, Little Rock, and Dr. Harold W. Sterling, manager of the Veterans Administration Hospital, North Little Rock, head the local arrangements committee.

Grants by Lasdon Foundation.—William S. Lasdon, president of the Lasdon Foundation, Inc., Yonkers, N. Y., in an eight months' report of the foundation's philanthropic activities, announces that 26 grants, totaling $178,092.54, were made to universities and medical centers throughout the United States and abroad for research in health and disease. These grants include a special grant of $15,000 to Harvard Medical School, Boston, for further studies in the transplantation of the human kidney, and a grant of $15,856 to Washington University School of Medicine, St. Louis, for research into certain phases of hypertension and other vascular diseases, under the direction of Dr. Henry A. Schroeder, St. Louis.

Award for Paper on Diabetes.—Competition is open for the annual award offered by the American Diabetes Association to medical students and interns for the best paper in the field of diabetes and basic metabolic problems. Candidates may select any subject related to diabetes for a report of original studies, a biographical or historical note, a case report with suitable comment, or a review of the literature. Manuscripts (6-18 pages, typewritten with double spacing) should be submitted by April 1, 1954, to *The Journal of the American Diabetes Association,* 11 W. 42nd St., New York 36. The prize of $250 again is made possible by the generosity of the St. Louis Diabetes Association.

Longevity in Wage Earners.—According to the Metropolitan Life Insurance Company, New York, experience among their industrial policyholders shows that 1952 registered the ninth year of consecutive rise in longevity, the average length of life of America's wage earners and their families reaching a new high of 68.5 years. The gain in average lifetime amounts to 5 years since 1941, 10 years since 1932, and 22 years since 1911-1912. In 1879-1889 the average lifetime was only 34 years, less than half that for 1952. The company reports that, whereas in 1911-1912 the average lifetime for industrial policyholders was about 6½ years less than that for the general population, currently the two are on a par.

Teaching Institutes.—The Association of American Medical Colleges is undertaking a series of teaching institutes; the first, Oct. 19-23 in Atlantic City, will concern itself with physiology, biochemistry, and pharmacology. Each institute is planned to bring together, by invitation, a group of medical educators. The first institute, which will precede the annual meeting of the association, Oct. 26-28, is being financed by the National Heart Institute of the U. S. Public Health Service, the medical schools, and the Association of American Medical Colleges. Future institutes are planned to cover the following areas:

Pathology, microbiology, immunology, and genetics (1954).
Anatomy, histology, embryology, and anthropology (1955).
Medical ecology (1956).
Clinical teaching including the internship (1957).
Specialty training and the continuing education of the physician (1958).

Society News.—The **American Association of Obstetricians, Gynecologists and Abdominal Surgeons** has elected Dr. Herbert E. Schmitz, Chicago, president; Dr. Thaddeus L. Montgomery, Philadelphia, president-elect; Dr. Frederick J. Lynch, Boston, vice-president; Dr. Frank R. Lock, Winston-Salem, N. C., secretary; Dr. E. Stewart Taylor, Denver, assistant secretary; and Dr. Ward F. Seeley, Detroit, treasurer. The next annual meeting of the association will be held at the Homestead, Hot Springs, Va., Sept. 9-11, 1954. Communications should be addressed to Dr. Frank R. Lock, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C.——At its fall meeting at Harrison Hot Springs in British Columbia, the **North Pacific Society of Internal Medicine** elected Dr. Howard P. Lewis, Portland, president; Dr. Edwin G. Bannick, Seattle, vice-president; Dr. Clarence C. Pearson, Seattle, secretary-treasurer; and Dr. Roger H. Keane, Portland, Ore., a member of the executive committee. In 1954 the spring meeting (March) will be held in Spokane, Wash. and the fall meeting (Sept.) in Victoria, Canada.

Safety Congress in Chicago.—The National Safety Council announces that the 41st National Safety Congress and Exposition will be held in Chicago Oct. 19-23. On Monday, 2:15 p. m. Dr. Kozme F. Kapov, medical director, Armour and Company, Chicago, will serve as leader for the panel discussion, "The Industrial Back—or How to Prevent This Type of Injury and Claim," at the Congress Hotel. Tuesday morning Dr. Vlado A. Getting, professor of public health practice, University of Michigan, Ann Arbor, will preside at a meeting in which reports on community organizations for home safety will be presented at the Conrad Hilton Hotel. Dr. Harry Wain, health officer, City-County Health Department, Mansfield, Ohio, will describe "An Action Program for the Health Department." Wednesday morning at the Conrad Hilton Hotel, there will be a symposium on industrial lighting and seeing in which Dr. Arthur L. Koven, Philadelphia, will present "Which Rays Injure the Eyes," and Dr. Hedwig S. Kuhn, Hammond, Ind., will discuss "Eyes—Facts and Fallacies." Wednesday morning at the Conrad Hilton, Dr. Gerald Gordon, Wilmington, Del., will have as his topic "Safety from the Standpoint of the Psychiatrist," and Dr. Frederick W. Slobe, Chicago, will discuss "Medical Care of Employees." Dr. Jermyn F. McCahan, New York, will discuss "Pre-Employment and Periodic Physical Examinations" at the Hamilton Hotel, and Dr. Maxwell M. Corbett, Chicago, will represent medicine in the panel discussion, "Job Placement Physical Examinations," at the Hamilton Hotel. At 3 p. m. at the Conrad Hilton Hotel, Dr. Ernest W. Miller, Milwaukee, will consider "Why is Electric Shock Serious?" Thursday at the Conrad Hilton, Dr. Richard J. Bennett Jr., Chicago, will open the afternoon session on safety in fabricating and warehousing with a discussion, "Health in Steel Warehousing Operation."

Registration fee for the congress and exposition is $5. Registration and information desks will be located in the Conrad Hilton, Blackstone, Congress, Hamilton, La Salle, Morrison, and Palmer House hotels.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.
1954 Annual Meeting, San Francisco, June 21-25.
1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.
1955 Annual Meeting, Atlantic City, N. J., June 6-10.
1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy for Cerebral Palsy, Western Hills Hotel, Fort Worth, Texas, Oct 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Association of Blood Banks, LaSalle Hotel, Chicago, Oct. 17-20. Miss Marjorie Saunders, 3500 Gaston Ave., Dallas 4, Texas, Secretary.

American Cancer Society, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Cardiology, Hotel Statler, Cleveland, Ohio, Nov. 6-7. Dr. Philip Reichert, 480 Park Ave., New York 22, Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Knickerbocker, Chicago, Nov. 1-2. Dr. O. J. Pollak, P. O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, Hotel Claridge, Atlantic City, N. J., Oct. 26-28. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 11-12. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Association of State and Territorial Health Officers, Washington Hotel, Washington, D. C., Nov. 4-7. Dr. John D. Porterfield, 306 Ohio Depts. Bldg., Columbus 15, Ohio, Secretary.

Central Association of Obstetricians and Gynecologists, The Shamrock, Houston, Texas, Nov. 5-7. Dr. Harold L. Gainey, Suite 602, 116 South Michigan Ave., Chicago 3, Secretary.

Conference of Public Health Veterinarians, Hotel New Yorker, New York, Nov. 9. Dr. James Lieberman, U. S. Public Health Service, Washington 25, D. C., Secretary.

Congress of Neurological Surgeons, Roosevelt Hotel, New Orleans, Nov. 12-14. Dr. B. W. Cannon, 1092 Madison Ave., Memphis, Tenn., Secretary.

Constantinian Society, Battery Park Hotel, Asheville, N. C., Oct. 18-21. Dr. C. F. Shook, Medical Director, Owens-Illinois Glass Company, Toledo 1, Ohio, Secretary.

Indiana State Medical Association, French Lick, Oct. 19-21. Mr. James A. Waggener, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

Interstate Post Graduate Medical Association of North America, Palmer House, Chicago, Nov. 2-5. Dr. E. R. Schmidt, 1300 University Ave, Madison 5, Wisconsin, Secretary.

Inter-Society Cytology Council, Philadelphia, Nov. 19-20. Dr. Paul F. Fletcher, 634 North Grand Blvd., St. Louis 3, Secretary.

Midwestern Section of American Federation for Clinical Research, Congress Hotel, Chicago, Oct. 29. Dr. Robert J. Glaser, 600 S. Kingshighway Blvd., St. Louis 10, Secretary.

National Association for Mental Health, Hotel Carter, Cleveland, Oct. 31-Nov. 2. Dr. George S. Stevenson, 1790 Broadway, New York 19, Medical Director.

National Society for Crippled Children and Adults, Palmer House, Chicago, Nov 12-14. Mr. Lawrence J. Linck, 11 South LaSalle St., Chicago 3, Secretary.

New England Obstetrical and Gynecological Society, Hotel Somerset, Boston, Oct. 28. Dr. Carmi R. Alden, 270 Commonwealth Ave., Boston, Secretary.

North Pacific Surgical Association, Victoria, B. C., Nov. 20-21. Dr. John A. Duncan, 509 Olive Way, Seattle, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Oct. 26-29. Miss Alma F. O'Donnell, 512 Medical Arts Bldg., Oklahoma City 2, Executive Secretary.

Omaha Mid-West Clinical Society, Hotel Paxton, Omaha, Oct. 26-30. Miss Irene Rau, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Pacific Northwest Society of Pathologists, Eugene, Oregon, Nov. 6-7. Dr. John L. Whitaker, 315 South K St., Tacoma 3, Wash., Secretary.

Regional Meetings, American College of Physicians:

- Michigan, H. H. Rackham Auditorium, Ann Arbor, Dec. 5. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Governor.
- Midwest—Ill., Ind., Iowa, Minn., Wis.—Hotel Schroeder, Milwaukee, Nov. 21. Dr. Francis D. Murphy, 536 West Wisconsin Ave., Milwaukee 3, Chairman.
- New England—Conn., Maine, Mass., N. H., R. I., Vt.—Hartford, Conn., Oct. 28. Dr. John C. Leonard, 80 Seymour St., Hartford 15, Conn., Chairman.
- New Jersey, Trenton, Nov. 4. Dr. Edward C. Klein Jr., 73 Lincoln Park, Newark 2, Governor.
- North Carolina, Chapel Hill, Dec. 3. Dr. Elbert L. Persons, Duke Hospital, Durham, Governor.

Regional Meetings, American Rheumatism Association:

- Ohio and Western Pennsylvania, Mayflower Hotel, Akron, Ohio, Nov. 11. Dr. Roger Q. Davis, 1405 Goodyear Blvd., Akron 5, Ohio, Chairman.

Southern Medical Association, Municipal Auditorium, Atlanta, Ga., Oct. 26-29. Mr. C. P. Loranz, 1020 Empire Bldg., Birmingham 3, Ala., Secretary.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 8-10. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Southwestern Medical Association, Pioneer Hotel, Tucson, Ariz., Oct. 29-31. Dr. C. C. Stapp, 800 Montana St., El Paso, Texas, Secretary.

Virginia, Medical Society of, Hotel Roanoke, Roanoke, Oct. 18-21. Mr. Robert I. Howard, 1105 W. Franklin St., Richmond 20, Executive Secretary.

Western Surgical Association, The Drake, Chicago, Dec. 3-5. Dr. Michael Mason, 154 East Erie St., Chicago 11, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. MacRae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Conference of International Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

Congress of International Anesthesia Research Society, Chateau Frontenac, Quebec, Canada, October 26-29. Dr. A. William Friend, 515 Nome Ave., Akron 20, Ohio, Chairman, Program Committee.

Congress of International Association for the Prevention of Blindness, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

Congress of International Society of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of Cardiology, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-15, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

International Congress of Clinical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A. Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6^{e}, France, Secretary.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of Industrial Medicine, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

International Congress of Internal Medicine, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress of Nutrition, Amsterdam, Netherlands, Sept. 14-18, 1954. For information write: Dr. M. van Eekelen, Centraal Instituut voor Voedingsonderzoek T.N.O., 61 Catharynesingel, Utrecht, Netherlands.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of *Ophthalmology*, University of Montreal and McGill University, Montreal, Canada, Sept. 10-11, 1954, and Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 12-17, 1954. Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minnesota, U. S. A., Secretary-General.

International Congress of Orthopedic Surgery and Traumatology, Berne, Switzerland, Aug 30-Sept. 3, 1954. For information write: Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Poliomyelitis Congress, Rome, Italy, Sept. 6-10, 1954. Mr. Stanley E. Henwood, 120 Broadway, New York 5, N. Y., U. S. A., Executive Secretary.

International Society of Blood Transfusion, Paris, France, Sept. 12-19. For information write: Colonel Julliard, Societe Internationale de Transfusion Sanguine, 53 Boulevard Diderot, Paris 12^{e}, France.

International Society for Cell Biology, Leiden, Netherlands, Sept. 2-9, 1954. Professor Peter J. Gaillard, University of Leiden, Leiden, Netherlands, Secretary.

International Society of Geographical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Professor Fred C. Roulet, Hebelstrasse 24, Basle, Switzerland, Secretary-General.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

World Congress of International Society for the Welfare of Cripples, The Hague, Netherlands, Sept. 13-17, 1954. For information write: D. C. Schaap, Centrale Vereniging, Apeldoorschweg 51, Arnhem, Netherlands.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Arizona:* *Examination.* Phoenix, Oct. 22-23. *Endorsement.* Phoenix, Oct. 24. Executive Secretary, Mr. Robert Carpenter, 401 Security Bldg., Phoenix.

Arkansas:* *Examination.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

Colorado:* *Examination.* Denver, Dec. 15-16. Final date for filing application is Nov. 14. Executive *Secretary, Miss* Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* New Haven, Nov. 10-11. Reciprocity actions are taken continuously. Secretary to the Board, Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic.* Derby, Nov. 10-11. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

Florida:* *Examination.* Jacksonville, Nov 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Hawaii: Honolulu, Jan. 11-14. *Examination.* Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, *Mr. Armand L.* Bird, 364 Sonna Bldg., Boise.

Iowa:* *Examination.* Des Moines, Dec. 7-9. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Topeka, Dec. 9-10. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 7-9. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville.

Maine: Portland, Nov. 12-13. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination.* Baltimore, Dec. 8-11. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

Minnesota:* Minneapolis, Oct. 20-22. Sec., Dr. E. M. Jones, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Missouri: Kansas City, Oct. 22-24. Ex. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Nebraska:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

New Jersey: *Examination.* Trenton, Oct. 20-23. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

North Dakota: *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C, J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, Dec. 17-19. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Pennsylvania: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

South Dakota:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination and Reciprocity.* Salt Lake City, Nov. 17. Director, Mr. Frank E. Lees, 314 State Capitol, Salt Lake City 1.

A. McGregor Hospital; died Aug. 26, aged 45, of acute cardiac dilatation.

McQueen, Arthur Frederick, Amherst, Ohio; University of Wooster Medical Department, Cleveland, 1911; served during World War I; for four years on the school board; for many years member of the city council; chosen "Man of the Year" for 1952 by the Amherst Chamber of Commerce; affiliated with St. Joseph's Hospital in Lorain and the Amherst Hospital; died July 18, aged 69, of cerebral hemorrhage.

Marshall, Benjamin Maxwell ⊕ Eureka, Calif.; College of Physicians and Surgeons of San Francisco, 1902; served as chairman of the board of education; affiliated with General Hospital, where he died Aug. 10, aged 77, of arteriosclerosis.

Mitchell, James Henry ⊕ Pittsburg, Texas; University of Louisville (Ky.) Medical Department, 1894; served as county health officer and Selective Service examiner; president of the Pittsburg Medical and Surgical Hospital; died April 3, aged 81, of coronary occlusion.

Moore, Thomas Kenney, Sharon Center, Ohio; Jefferson Medical College of Philadelphia, 1899; past president of the Summit County Medical Society; affiliated with Peoples and Children's hospitals and on the honorary staff of the City Hospital in Akron, where he died Aug. 8, aged 80, of carcinoma of the stomach.

Morris, Zenella Elizabeth Nelson ⊕ Stockport, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1894; past president of the Van Buren County Medical Society; died in Keosauqua June 15, aged 89, of cerebral thrombosis.

Munn, Wayne Alonzo ⊕ Janesville, Wis.; Northwestern University Medical School, Chicago, 1906; preceptor, University of Wisconsin, Madison from 1930 to 1952; an Associate Fellow of the American Medical Association; fellow of the American College of Surgeons; past president of the Rock County Medical Society; served during World War I; affiliated with Mercy Hospital, where he was president of the staff; died Aug. 8, aged 71, of coronary thrombosis.

Neel, William Hal ⊕ Bowling Green, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1913; served on the staff of the City Hospital, where he died July 28, aged 63, of duodenal ulcer.

Neff, Charles Otis ⊕ Louisville, Ky.; Southwestern Homeopathic Medical College and Hospital, Louisville, 1905; for two terms president of the Kentucky State Medical Association; served during World War I; died July 20, aged 75.

Newcomb, James H., Richton, Miss.; Atlanta School of Medicine, 1912; past president of the South Mississippi Medical Society; colonel on the staff of Gov. Hugh White at the time of his death; died Aug. 30, aged 70, of a heart attack.

Nicholls, James William ⊕ Helena, Ark.; Chattanooga (Tenn.) Medical College, 1902; served as vice-president of the Phillips County Medical Society; on the staff of the Helena Hospital; died July 7, aged 70, of heart failure.

Nolen, Beverly Toon ⊕ Franklin, Tenn.; Vanderbilt University School of Medicine, Nashville, 1906; served during World War I; formerly health officer; died in St. Thomas Hospital, Nashville, Aug. 7, aged 72, of coronary thrombosis.

Ogden, Leon Gray ⊕ Holley, N. Y.; Albany (N. Y.) Medical College, 1899; past president of the Orleans County Medical Society; formerly county coroner; served as health officer; died in North Bay, Ontario, Canada, Aug. 22, aged 78, of coronary thrombosis.

Ognibene, Frank Anthony ⊕ Fredonia, N. Y.; University of Buffalo School of Medicine, 1914; member of the American Society of Anesthesiologists; affiliated with Brook Memorial Hospital in Dunkirk; died July 28, aged 61, of coronary thrombosis.

Parham, Ben Otis, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1948; resident in neurosurgery at the Ochsner Foundation Hospital, where he died Aug. 22, aged 27.

Perrin, Stuart Henry ⊕ Superior, Wis.; University of Wisconsin Medical School, Madison, 1928; died at Lake Nebagamon May 16, aged 50, of coronary thrombosis.

Peterson, Charles Frederick ⊕ Independence, Wis.; Northwestern University Medical School, Chicago, 1907; in July 1952 the Independence Lions Club held a "Dr. Peterson Day" to mark his long years of service; for 36 years member of the school board; died June 30, aged 82, of chronic myocarditis.

Petzke, Ernest A. ⊕ Hixton, Wis.; Northwestern University Medical School, Chicago, 1896; died July 7, aged 81, of a heart attack.

Phillips, Bruce Gretton, Bay Pines, Fla.; University and Bellevue Hospital Medical College, New York, 1899; died July 11, aged 79, of bronchopneumonia.

Pinkerton, William Alfred ⊕ North Garden, Va.; University of Virginia Department of Medicine, Charlottesville, 1900; died in Charlottesville July 8, aged 76, of congestive heart failure.

Privka, Arkadijs Aleksandrs, St. Paul, Minn.; Latvijas Universitāte Medicinas Fakultate, Riga, 1936; died in Ancker Hospital July 14, aged 46, of carcinoma of the rectosigmoid, following resection.

Putney, Robert Hubbard ⊕ Elm City, N. C.; Medical College of Virginia, Richmond, 1914; died in Park View Hospital in Rocky Mount July 9, aged 63, of pneumonia.

Quinn, Patrick John ⊕ Rochester, N. Y.; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1908; on the staff of St. Mary's Hospital; died July 27, aged 70, of carcinoma of the tongue.

Radford, Arthur Franklin, Kansas City, Mo.; Meharry Medical College, Nashville, Tenn., 1914; died in the General Hospital July 8, aged 63.

Ranson, J. Lester, Sr. ⊕ Charlotte, N. C.; North Carolina Medical College, Charlotte, 1911; also a graduate in pharmacy; served as secretary and president of the Mecklenburg County Medical Society; affiliated with Presbyterian Hospital, where he died Aug. 21, aged 69, of coronary thrombosis.

Remington, Alvah Childs ⊕ Rochester, N. Y.; University of Buffalo School of Medicine, 1897; consulting physician at the Rochester State Hospital; affiliated with Monroe County Infirmary and St. Mary's Hospital, where he died Aug. 17, aged 81, of cerebral sclerosis and fracture of humerus due to an accidental fall.

Robertson, Beridge Ruth, Demarest, N. J.; Columbia University College of Physicians and Surgeons, New York, 1941; associate member of the American Medical Association; died Sept. 7, aged 35, of cancer.

Robinson, Shelby Louise Boynton ⊕ Los Angeles; Meharry Medical College, Nashville, Tenn., 1909; died Aug. 18, aged 64, of terminal pneumonia and adenocarcinoma of the breast.

Ross, Emmy Marie Sophie ⊕ St. Louis; Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, 1918; affiliated with Christian Hospital, De Paul Hospital, Missouri Baptist Hospital, and the Deaconess Hospital, where she died July 29, aged 63, of tumor of the brain.

Sancetta, Biagis, Cleveland; Regia Università degli Studi di Palermo Facolta di Medicina e Chirurgia, Italy, 1902; died in the University Hospitals July 13, aged 75.

Savitsky, Nathan ⊕ New York City; University and Bellevue Hospital Medical College, New York City, 1927; specialist certified by the American Board of Psychiatry and Neurology; member of the American Neurological Association, American Psychiatric Association, and the Association for Research in Nervous and Mental Diseases; past president of the Bronx County Neurological Society and the Hebrew Medical Society; affiliated with Lebanon, Morrisania, and Seton hospitals; died in Mount Sinai Hospital Sept. 4, aged 50.

Shelton, Harold Jordan ⊕ Webster Groves, Mo.; St. Louis University School of Medicine, 1934; member of the American Academy of General Practice; fellow of the American College of Surgeons; affiliated with St. Anthony's Hospital, St. Mary's Group of Hospitals, and Alexian Brothers Hospital in St. Louis, where he died July 4, aged 45.

Smith, James Monroe ⊕ Cochran, Ga.; Atlanta School of Medicine, 1911; died in Macon July 31, aged 77, of cerebral hemorrhage and carcinoma of the bladder.

Smythe, Jay Bingham, Holton, Kan.; Hahnemann Medical College of the Kansas City University, Kansas City, 1901; died in Holton Hospital July 13, aged 75, of congestive heart failure.

Sweet, Grover Cleveland, Rocky Hill, Conn.; College of Physicians and Surgeons, Baltimore, 1912; administrator of the State of Connecticut Veterans Home and Hospital, where he died Aug. 15, aged 67, of coronary thrombosis.

Thompson, Noah Howard ⊕ Bedford, Va.; Rush Medical College, Chicago, 1894; member of the Indiana State Medical Association; died June 28, aged 81, of myocardial failure.

Tinder, J. Stanley, Parsons, Kan.; Chicago Physio-Medical Institute, 1898; died June 25, aged 81, of coronary occlusion.

Torpy, Thomas William ⊕ Omaha; John A. Creighton Medical College, 1919; formerly assistant professor of surgery at his alma mater; member of the American Academy of General Practice; affiliated with St. Joseph's Hospital and St. Catherine's Hospital, where he died July 9, aged 60, of bronchogenic carcinoma.

Turner, Henry Cromwell ⊕ West Covina, Calif.; University of Virginia Department of Medicine, Charlottesville, 1927; member of the Idaho State Medical Association; specialist certified by the American Board of Radiology; formerly practiced in Pocatello, Idaho, where he was on the staff of St. Anthony Mercy Hospital and Pocatello General Hospital; died in Covina July 19, aged 54, of coronary occlusion.

Utley, Vernon T., Parkin, Ark.; University of Arkansas School of Medicine, Little Rock, 1905; for many years county health officer; died in Cross County Hospital, Wynne, Aug. 14, aged 78, of heart disease.

Wade, Edward H., Augusta, Ill.; Eclectic Medical Institute, Cincinnati, 1903; died in St. Elizabeth's Hospital, Hannibal, Mo., July 3, aged 76.

Ward, Harry Norbert ⊕ Hamilton, Ohio; University of Cincinnati College of Medicine, 1925; affiliated with Mercy Hospital and Fort Hamilton Hospital, where he died Aug. 22, aged 52, of coronary occlusion.

Webb, Roy, Delray Beach, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1909; died July 18, aged 69, in coma due to hepatic cirrhosis.

Whelan, Edward James ⊕ Savannah, Ga.; Georgetown University School of Medicine, Washington, D. C., 1924; fellow of the American College of Surgeons; served as president and chief of staff of St. Joseph's Hospital; affiliated with Warren A. Candler Hospital and Oglethorpe Sanatorium; died July 10, aged 53, of angina pectoris.

White, Eston Delaney ⊕ Miami, Fla.; University of Tennessee College of Medicine, Memphis, 1941; died July 28, aged 47, of coronary thrombosis.

White, Frank Melvin, Miles, Va.; New York Homeopathic Medical College and Flower Hospital, New York, 1915; died July 30, aged 73, of cerebral embolism.

Williams, Samuel Hanson, Crofton, Ky.; University of Tennessee Medical Department, Nashville, Tenn., 1894; president of the Hopkinsville Milling Company; died in Jennie Stuart Hospital, Hopkinsville, Aug. 18, aged 82, of arteriosclerotic cardiovascular and renal disease.

Winter, Louis Carl ⊕ Wilton Junction, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1901; died in the Bellevue Hospital, Muscatine, May 10, aged 80, of cerebral thrombosis and arteriosclerosis.

Wollin, Maurice, New York City; Fordham University School of Medicine, New York, 1918; served during World War I; for many years school physician for the city board of education; died July 14, aged 62, of coronary occlusion.

DIED WHILE IN MILITARY SERVICE

Cox, Wesley Cintra ⊕ Col. U. S. Army, retired; born in Brooklyn, April 21, 1891; Columbia University College of Physicians and Surgeons, New York, 1916; subsequently took graduate training at the Army Medical School, Washington, D. C., and Johns Hopkins University, Baltimore; specialist certified by the American Board of Preventive Medicine and Public Health; fellow of the American College of Physicians, American Public Health Association, and the American Geriatrics Association; member of the American Society of Tropical Medicine and Hygiene, Industrial Medical Association, American Association of Industrial Hygienists, and the Association of Military Surgeons of the United States; began his Army career in 1917 when he joined the medical corps reserve as first lieutenant; the following year was commissioned first lieutenant in the regular Army; during his 36 years of service held posts as chief of the laboratory, Camp Jackson, S. C., in 1921, epidemiologist, Fort Dix, N. J., 1921-1922, serologist and chief, laboratory, Eighth Army Area, 1926-1931, chief, laboratory, and medical inspector, Fort Leavenworth, Kan., 1931-1934; was bacteriologist and instructor, 1917-1921, and bacteriologist, serologist, and instructor, 1925-1926 at the Army Medical School, Washington, D. C., and bacteriologist and instructor, Walter Reed General Hospital, 1934-1937; served in the Panama Canal Department as bacteriologist in 1922, leaving in 1925 and returning in 1939 to spend seven more years in the Canal Zone; served as assistant surgeon, headquarters, Caribbean Command, 1946; retired April 30, 1951; awarded the Legion of Merit, the Army Commendation ribbon, and by the President of Panama, the Order of Vasco Nuñez de Balboa, Grade of Commander; was commanding officer of the Army Environmental Health Laboratory at the Army Chemical Center, Edgewood, Md.; died in Richmond, Va., May 22, while serving on active duty, aged 62, of cerebral hemorrhage.

Collins, Leonard James Jr. ⊕ Sherman, Texas; born in Fort Worth, Texas, April 21, 1924; Southwestern Medical School of the University of Texas, Dallas, 1947; interned at the Baylor University Hospital in Dallas; formerly a resident in internal medicine at Grady Memorial Hospital in Atlanta, Ga.; during his active naval career served at the Naval Hospital, Corpus Christi, aboard the USS General M. Randall, and in July of 1951 was released to inactive duty; volunteered for duty, and was ordered into active military service in May, 1952, serving as a lieutenant in the U. S. Naval Reserve; reported to the Naval Hospital, Jacksonville, Fla., on July 15, 1952, and was serving at this hospital at the time of his death June 6, aged 29, of pulmonary edema and cardiac arrest.

Rhamy, Richard Alan, Sidney, Ohio; Indiana University School of Medicine, Indianapolis, 1951; interned at the Cincinnati General Hospital; served a residency at the Veterans Administration Center in Dayton; entered the U. S. Air Force as a first lieutenant April 19, 1953; died in the U. S. Air Force School of Aviation Medicine at Randolph Air Force Base, Texas, July 1, aged 24, of traumatic bilateral pneumothorax with aeroembolism.

Keane, James Patrick ⊕ Fairview Park, Ohio; St. Louis University School of Medicine, 1948; interned at St. John's Hospital in Cleveland, where he served a residency; formerly a fellow in internal medicine at the Cleveland Clinic Hospital; affiliated with Fairview Park Hospital in Cleveland; first lieutenant in the air force at Lockbourne Air Force Base; killed in an airplane accident at North Olmstead, July 30, aged 29.

Lutes, Lester L., ⊕ Major, M.C., U. S. Air Force, Elizabethton, Tenn.; University of Tennessee College of Medicine, Memphis, 1941; interned at the California Hospital in Los Angeles; served as health director of Carter, Unicoi, and Johnston counties; flight surgeon stationed in England; killed in an automobile accident near Cheltenham, England, April 14, aged 46.

Owen, William Hamilton, Detroit, Mich.; Wayne University College of Medicine, Detroit, 1952; interned at the Walter Reed Army Hospital no. 12 in Washington, D. C.; first lieutenant, medical corps, U. S. Army Reserve; died in Ann Arbor, July 27, aged 27, of poliomyelitis.

GOVERNMENT SERVICES

ARMY

General Denit Retires.—Major Gen. Guy B. Denit, former surgeon of the U. S. Army in Europe, retired on Sept. 30 after more than 38 years of active duty. Gen. Denit was assistant surgeon of the 29th Division in Europe during World War I and was chief of the planning division of the Surgeon General's Office from 1928 to 1932. During World War II, he was chief surgeon of the Atlantic Base section in Casablanca and, later, chief surgeon of American forces in the Pacific theater. During 1946 and 1947 he was chief of the plans and operations division of the Surgeon General's Office. He has been chief of medical services for the European Command since 1948. An honor graduate of the Army Medical School and the Medical Field Service School, General Denit also attended the Command and General Staff School and the Army War College. In 1947 the Medical College of Virginia conferred on him the honorary degree of Doctor of Science. He has been awarded the Distinguished Service medal, the Legion of Merit, the Bronze star, the Army Commendation ribbon, and several campaign ribbons.

NAVY

Guest Lecture Series.—The first lecture of the 1953-1954 Guest Lecture Series, under the auspices of the Naval Medical School, Bethesda, Md., was presented Sept. 25 by Dr. Isador S. Ravdin, professor of surgery, University of Pennsylvania Medical School. The lecture was entitled "Some Problems Facing Military Medicine." Dr. Ravdin recently toured medical installations of the armed forces in the Far East. During World War II he saw service in the India-Burma-China theater of operations and advanced to the rank of brigadier general.

OFFICE OF DEFENSE MOBILIZATION

Personal.—Dr. Francis J. Braceland of Hartford, Conn., who was appointed by President Eisenhower to the National Advisory Committee of the Selective Service System, has been appointed by the Director of Defense Mobilization to the Health Resources Advisory Committee. Dr. Braceland's appointment will fill the vacancy on the two committees, the membership of which is identical, created by the resignation of Dr. James C. Sargent, Milwaukee, Wis. Dr. Sargent, who has served on the committees since their inception in 1950, has been appointed a consultant to the two groups.

PUBLIC HEALTH SERVICE

Study of Amyotrophic Lateral Sclerosis.—A major study of amyotrophic lateral sclerosis has just been initiated on Guam. This investigation, in which the Public Health Service, the Navy Bureau of Medicine and Surgery, and the Department of Interior are participating, will be headed by Dr. Leonard T. Kurland, chief epidemiologist of the Public Health Service's National Institute of Neurological Diseases and Blindness, who left for Guam this month. Information now available indicates that this crippling, fatal disease is highly prevalent on Guam.

The chances for determining the possible roles of heredity and environment in the development of amyotrophic lateral sclerosis are especially good on Guam because of the relatively fixed population.

Dr. Donald Mulder, U. S. Navy, and Drs. K. K. Waering and S. Tillema of the government of Guam will cooperate in the present study, which will go on for about two months. The research team will examine several groups of natives in addition to those presently affected with this disease. By investigating the siblings of those affected, they hope to determine why one member of the family has incurred the disorder, and others not. Examination of a random group of natives on Guam may also help isolate the special conditions that may be responsible for the disease. Finally, the research team will study the natives on a neighboring island in order to determine whether the problem is typical of Guam alone or of other areas in the Marianas as well.

VETERANS ADMINISTRATION

New Hospital Dedicated in West Haven.—Dedication ceremonies at the opening of the new 15 million dollar Veterans Administration Hospital in West Haven, Conn., were held Sept. 13. The dedicatory address was delivered by Harvey V. Higley, newly appointed administrator of veterans' affairs, and the response was by Dr. Lewis G. Beardsley, manager of the hospital. Vice-Adm. Joel T. Boone (MC), U. S. Navy (Ret.), chief medical director of the Veterans Administration, spoke on the medical care program. The new hospital is the 47th to be completed under the construction program approved after World War II. It contains 872 beds, of which 396 are allocated to the tuberculosis unit, 332 to general medical and surgical cases, and 144 to the neuropsychiatric unit.

Personal.—Dr. Edwin J. Rose, formerly assistant director of the hospital operations service in the VA central office, Washington, D. C., became manager of the Mount Alto Veterans Hospital, Washington, D. C., Sept. 8, and Dr. Linus A. Zink, formerly manager of Mount Alto Hospital, became acting director of hospitals and clinics in the central office, a new post under the VA's reorganization.

Personal.—Dr. John N. Rich, acting director of the medical division of the New York Regional Veterans Administration office, has been named chief medical officer for the Veterans Administration regional office at Huntington, W. Va., succeeding Dr. Leo F. Steindler, who retired in February, 1953.

MISCELLANEOUS

Scientific Translations Center.—A center for photoduplicating foreign scientific translations has been established by the National Science Foundation in the science division of the Library of Congress. Partial support for the project was contributed by the U. S. Atomic Energy Commission. Establishment of the translations center is part of a foundation program to assist American scientists keep informed about scientific progress in other countries. Scientific translations will be collected from many sources, including government agencies, scientific societies, industrial laboratories, and universities. Initially, the center will put major emphasis on translations from Russian scientific journals, although it is hoped eventually to add material from other languages. Monthly lists of translations newly received will be issued by the Library of Congress. The monthly listings will include notices of translations that are available by direct purchase from commercial and other translating services, but the center will not supply photocopies of such material.

The price list established by the center for copies of translations is as follows: photostats or enlarged microprints, 1 to 10 pages, $1.25 and, 11 to 15 pages, $1.75; microfilms, 1 to 50 pages, $1.00. Inquiries about the new service should be addressed to the Scientific Translations Center, Science Division, Library of Congress, Washington 25, D. C.

FOREIGN LETTERS

BELGIUM

Ethics of Psychiatry and Clinical Psychology.—The Belgian Society of Mental Medicine, with Dr. Raedemaekers, president, presiding at a meeting on March 28, studied problems in ethics in psychiatry and clinical psychology. Professor Nyssen endeavored to define the boundaries between psychiatry and psychology and in so doing studied the principles that should guide collaboration between physicians and psychologists.

Psychology and psychiatry are two mutually supportive sciences, and there is, in fact, no clear-cut frontier between them. The integration of psychology into clinical practice is a fact, but collaboration between physicians and psychologists who are not physicians raises delicate professional questions. The conception of clinical psychology held by various psychiatrists and the scope accorded to it by some of them require a clarification of the respective duties and powers of the supporters of the two sciences. Obviously, when the conclusions derived from examinations carried out according to certain techniques have to be applied in the domain of medicine, the physician alone is competent. The same is true when it is a question of using supplementary measures such as narcoanalysis, suggestions, and various stimuli.

When it is necessary to collaborate in scientific research or to use special techniques to assist in establishing a diagnosis or in understanding a personality, the collaboration of psychologists who are not physicians is often fruitful. It must be remembered, however, that tests have a limited value and that, while the psychological examination may reveal details the physician was unable to detect, it is he who must always have the last word. It is not that psychologists must accept subordination, but that the extent of their collaboration must be defined. In medical clinics, this presents no difficulty. There are, however, psychologists who, though not physicians, make diagnoses and even apply treatment without medical supervision. The author earnestly desires the collaboration of psychologists, but he refuses to give them autonomy in matters connected with the art of healing. This is the attitude generally accepted in the countries of western Europe.

Anthracosilicosis.—At the last session in 1951 of the Flemish Academy of Medicine, Van Mechelen discussed anthracosilicosis in Belgium on the basis of a statistical study of 49,216 workers at work, 500 sick workers, 17,386 workers receiving invalidism pensions, and 100 workers who had died from anthracosilicosis.

He showed that 21.42% of the 49,216 workers at work (which included almost half of all underground workers) were affected by anthracosilicosis. Among these, 13.75% were slightly affected, 5.91% moderately affected, and 1.76% seriously affected. Comparison with neighboring countries shows that the situation is equally serious everywhere.

The extent of the anthracosilicosis is proportional to the number of years of underground work. It is even more closely related to the kind of work performed. Contrary to the traditionally accepted opinion, coal workers are affected earlier and more severely in Belgium than rock workers.

Tuberculosis is rare among the workers at work. Only 0.23% of those examined were found to have active tuberculosis, and only 2.26% had cicatricial tuberculosis. These figures are much lower than the national average. Of 17,386 workers receiving invalidism pensions, 2.6% had pulmonary tuberculosis. Of 500 sick workers suffering from respiratory disease, 8% had progressive pulmonary tuberculosis. The percentage dropped from 11% in the reticular stage to 6% in the stage of anthracosilicotic condensation as a result of systematic exclusion of the tuberculous patients discovered. The sputum of 33 of the 100 workers who died of anthracosilicosis contained tubercle bacilli. Tuberculosis is thus a frequent complication of the final stage of anthracosilicosis, but it does not greatly affect the duration of life.

Technical improvement in mining techniques is the principal weapon in the fight against the pneumoconioses. Statistics extending from 1946 to 1950 show that it is being applied with increasing benefit in the Belgian collieries. The use of certain new engines for the cutting of coal greatly reduces the danger of pneumoconiosis. With total mechanization, human cutters are replaced by equipment that cuts, loads, and transports the coal. Experiments have been undertaken in Belgium by the Institut d'Hygiene des Mines to improve working conditions by the use of aerosols of sodium chloride solution that agglutinate the dangerous fine dusts. In addition, two large collieries are testing use of pneumodilating aerosols administered to workers from the mine depths at the end of their shifts.

Definition of a Physician.—Before the meeting of the Belgian Society of International Medical Law on March 13, 1953, in continuation of a debate on the need for codification of international medical law, Dr. Spaey presented a proposal tending to establish a distinction, in the application of humanitarian conventions, between a doctor of medicine and a physician giving care. This conception aroused the liveliest interest among the members, and at the same time a certain number of objections. These, brought forward especially by the physicians, were based primarily on the principle of the unity of medicine and medical action. Is it desirable, or even possible, to distinguish among medical activities, taken in the broad sense, those that contribute directly and those that contribute indirectly to health? Are preventive medicine and administrative medicine not just as important from the point of view of health as curative medicine, and would it not basically disorganize health service to refuse international protection to the physician who supervises the material installation of an ambulance or the organization of an evacuation line? In any case, the choice of criteria for the distinction would be difficult and their formulation and application would have to be entrusted to professional circles. In concluding the debate, the assembly decided that the distinction proposed by Dr. Spaey deserved a thorough study.

LONDON

Teaching of General Practice.—The report of the undergraduate education committee of the foundation council of the College of General Practitioners (*Brit. M. J.* 2:36 [July 4] 1953) points out that the student who chooses general practice requires instruction in academic medical knowledge, the application of this knowledge outside a hospital, and the doctor-patient relationship. It recalls the days of training by apprenticeship and points out that, while this system may have had its faults, "hospital consultants in those days were in close touch with general practice; many of them had been for a long time in general practice, some were still working as part-time practitioners, others were meeting practitioners frequently in consultation. Even in hospital, students at that time were taught the 'feel' of general practice . . . students now learn the science and principles of medicine without enough emphasis on their application in general practice, so that they remain unaware of the true nature of general practice and of the essential difference between the care of patients in hospital and in home surroundings. . . . The medical student is now taught almost entirely by members of hospital staffs who are specialists and who, to-day, may have had little personal experience of family doctoring; some of them do not even see patients in their homes in consultation with general practitioners. . . . Many medical students qualify to-day,

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

without having seen or spoken to a general practitioner. Some students, who might be happiest in general practice and be a powerful influence in raising its standard, deliberately avoid it, being unaware of the opportunities for good and satisfying work which it offers."

A table shows the replies to a questionnaire sent by the College of General Practitioners earlier this year to the deans of the 28 medical schools in Great Britain and Ireland. Only eight of the schools provide lectures on general practice, and two of these schools (Edinburgh and Manchester) have general practice teaching units. Fourteen schools make arrangements for students to work with general practitioners, but in four instances this is an "informal" arrangement; in two instances the length of the course is one day, while in another it is two evenings. The longest course is four weeks, and this is in only one school (Aberdeen). In one school the course concerns only obstetrics.

The committee urges that every medical school should co-opt general practitioners to its staff to teach students "certain important aspects of general practice." Such instruction can be given in a health center or a dispensary run by a medical school, or it can be organized jointly by a medical school and local general practitioners. The best time is probably at the beginning of the final year. Lectures in such a course should be given by men in active general practice, but the committee also "urge most strongly that more students should visit practitioners in their homes, in their surgeries, or on their rounds, and spend a few days with them. . . . This will give young practitioners a yardstick by which to measure all subsequent experience; in later years, either they will be proud of having done better than this first impression or they will know that they still have something to achieve."

Annual Report on Mental Hospitals.—The outstanding feature of the annual report of the Board of Control for 1952 is the persisting shortage of nurses and beds in the mental hospitals. At the end of the year, there were 149,353 patients reported to the board as under mental treatment, compared with 148,071 at the end of 1951. Of this total, 5,096 were private patients, 143,239 National Health Service patients, and 1,018 Broadmoor patients (patients detained under the acts relating to criminal lunatics). The state of overcrowding is indicated by the fact that, in 107 mental hospitals, there were "17,522 more patients than these hospitals were designed, according to prescribed standards, to receive." Of the available beds, 1,640 could not be used owing to shortage of staff. During the year, the number of trained male nurses increased from 9,156 to 9,275, but the number of trained female nurses decreased from 5,819 to 5,699. The report shows a continued decline in the incidence of tuberculosis in mental hospitals. The ratio of 6.1 cases per 1,000 patients is one of the lowest figures attained, and the death rate is now down to 2.1 per 1,000. Tuberculosis as a cause of death represents 3.2% of all deaths in mental hospitals, as compared with 2.5% of all deaths in the general population.

The steadily diminishing number of "licensed houses," privately owned houses or homes in which patients are cared for for payment, is an interesting commentary on the changing practice of medicine. In 1890, there were 31 metropolitan licensed houses and 58 provincial ones. When the National Health Service came into operation, in 1948, the corresponding numbers were 16 and 21; now they are 12 and 15.

Regional Planning of Diabetic Services.—On the recommendation of his Central Health Services Council, the Minister of Health has recommended to hospital authorities the following plan for the setting up of regional centers for the treatment of diabetics. It is considered that the requirements of diabetics can best be met by special regional centers to assist the family doctor and to permit concentration of expert supervision, the most advantageous use of existing medical facilities, and adequate treatment within a reasonable distance of the patient's home.

A regional diabetic service would normally include one or more such centers with facilities for the assessment and stabilization of the patient's condition, care of diabetic emergencies, training of patients with dietetic advice and instruction in use of insulin, and finally facilities for regular outpatient supervision. Such a center would need accommodation for inpatients and outpatients and should be linked with smaller peripheral clinics so situated that patients do not normally have to travel more than 25 to 30 miles for specialist consultation. It is suggested that one bed is needed for every 50 diabetics, to handle those patients who need admission for the initial assessment, stabilization, and training and to deal with relapses, complications, and emergencies. The incidence of diabetes has been estimated at three per thousand of the population of Great Britain. This means that for a population of around 350,000, some 20 beds would be needed to serve the 1,000 diabetics in that area.

The smaller centers need facilities for urine testing and blood sugar estimations. In addition to the medical staff, there should be a sister trained in dietetics and insulin administration, as well as one or more other nurses. The larger centers would provide a full range of ancillary facilities, especially pathological and radiological, with the necessary nursing staff, dietitians, part-time almoner, and chiropodist. The largest centers, probably in teaching hospitals, might have physicians specializing mainly in diabetes, but in most cases the centers will be in charge of a general physician with a special interest in diabetes. He should have had experience at an appropriate center before taking charge. Opportunities for any necessary training should be made available by the responsible hospital authorities to any physician new to this work.

Special arrangements should be made for the treatment of tuberculous, pregnant, and aged diabetics. In any one region, tuberculous diabetics should, wherever practicable, be concentrated in one sanatorium that should be closely linked with a diabetic clinic. Pregnant diabetics should be treated in large maternity units associated with general hospitals where special facilities for diabetics and special experience in the care of pregnant diabetics are available. Pregnant diabetics would be the responsibility of both the obstetrician and the physician concerned with diabetes. Aged diabetics should be able to use a diabetic clinic.

Medical Research Council.—The annual report of the Medical Research Council, which covers the year ended September, 1952, shows that the total expenditure of public funds was £1,587,544 on ordinary account and £137,704 on nonrecurrent account. Benefactions included $63,000 from the Rockefeller Foundation, $25,000 for travelling fellowships in medicine awarded by the council and $38,000 for the purchase of scientific equipment in the United States, and $36,000 from Eli Lilly & Company, $16,000 for travelling fellowships in medicine over a period of three years awarded by the council and $20,000 for the purchase of scientific equipment in the United States over a period of two years. The number of persons employed by the council for its own purposes was 1,427: 441 scientific staff members, of whom 152 are medically qualified, 519 technical, 264 administrative, and 156 full-time and 47 part-time maintenance staff members. This does not include the 50 African personnel employed at the field research station in the Gambia. As agents for the Ministry of Health, the council also employed 920 members of the Public Health Laboratory Service.

Developments referred to include conversion and new building work at the Hampstead laboratories to provide facilities for research on climatic physiology. Work has also been started on a new building at the Christie Hospital, Manchester, to house a betatron, while work is proceeding on the buildings to house the cyclotron and linear accelerator at Hammersmith for the radiotherapeutic research unit. At the end of the year, the organization consisted of the National Institute for Medical Research, 38 research units, 7 less formally constituted research groups, the antibiotics research station, the Laboratory Animals Bureau, and the field research station in Gambia. A new unit founded during the year was that for research on the experimental pathology of the skin. The report also gives details of the council's 68 "principal committees." There are nine separate committees concerned with various aspects of cortisone and corticotropin (ACTH).

Tuberculosis Hostels.—Under the National Health Service Act, county councils and county borough councils are empowered to provide residential hostels and to charge for the services provided to those accommodated. As a result of their experience in London and the neighboring county of Middlesex, W. Hartston and J. F. Macgregor outline a scheme for the organization of such residential hostels for the homeless tuberculous patient (*Tubercle,* 34:180 [July] 1953). The problem is an urban one, especially in large cities with acute housing shortage, and affects mostly men, especially elderly men trying to live on an old age pension or on National Insurance grants. Many have unstable, chronic conditions and divide their time between hospital and lodgings. "Often they are retained in hospital long after all available therapeutic measures have been exhausted and remain in hospital only because they have no homes to which they can be discharged." Hartston and Macgregor "look upon such hostels less as a means of reducing infectivity by segregation of the residents, though it may well act in this way to some extent, but more as a valuable social service providing the homeless ambulant phthisic with cheap good board, lodging and laundry and sympathetic helpful medical supervision." Such a hostel "should operate like a good quality boarding house and not like a nursing home or 'institution'."

While a hostel accommodating 40 or 50 persons is probably the most economical size, it is too large to allow the individual attention that is so desirable, and it is stated that hostels designed for 12 to 25 persons can be run satisfactorily. It is estimated that, in a fairly dense urban area, five hostel beds will be needed for 1,000 tuberculous men. A hostel for 20 men will cover the needs of an urban area of 1,200,000. It will need living accommodation for the resident staff, an office for the warden in charge, an examining room for the visiting physician, bedrooms, two recreation rooms, one or two dining rooms, a kitchen and annexes, three or four bathrooms, seven wash basins, four toilets, a sputum disposal sluice room, storage accommodation, a linen room, and a handicrafts workroom. Most bedrooms should be single; none should have more than four beds. It is considered useful to earmark one of the bedrooms, with two or three beds, as the "sick bay." "An attractive garden of at least half an acre is essential."

A hostel for 20 will need a warden, an assistant warden (these two should preferably be man and wife, with the wife acting as assistant warden who cooks and acts as domestic supervisor), and the equivalent of three full-time domestic assistants. All staff members should be over the age of 30 and should be tuberculin tested. Roentgenograms should be made of all and should be repeated every six months. A local general practitioner should act as hostel physician. Specialist care is provided by the physician of the local regional hospital board chest clinic.

Applications for hostel accommodation will come mainly from hospitals and chest clinics and will "relate to men who are homeless, temporarily or wholly disabled and perhaps at the moment living in common lodging houses. Some of these men will also have temperamental peculiarities which while tolerable in private lodgings would be a menace in a hostel." It is considered that the sifting of such applications should be in the hands of the Medical Officer of Health of the local health authority. The cost of building or converting available premises will vary considerably, but new equipment for 20 residents will cost approximately £2,500, and the average gross cost of maintaining a man will be around £4 10s.

Cancer Education.—This is one of the subjects dealt with in the annual report for 1952 of the Central Health Services Council, the body established under the National Health Service Act to advise the Minister of Health on problems arising out of the working of the service. Its membership is equally divided between physicians and laymen, the latter including persons with experience in hospital management, local government, nursing, pharmacy, and dentistry. The council recognizes that publicity schemes, if carried out with circumspection and in such a way as not to cause fear, must be of value in reducing the delay between the onset of symptoms and consultation of the general practitioner. Its members feel, however, that it is preferable, for the present, for the work on cancer education for the public to be carried out on a local basis by local authorities and voluntary organizations. The best way of handling the problem is not yet "clearly" known. Where there is so much room for experiment, local health authorities and voluntary organizations should be encouraged to devise different schemes. It is considered that "a most important" part of cancer education is education of physicians themselves in early diagnosis; such education on the early recognition of cancer is still deficient. The final recommendation to the Minister of Health is that it is undesirable at the present for any cancer publicity to be distributed by any central government organization direct to the general public. On the other hand, the minister encourages local health authorities and voluntary bodies to carry out exploratory schemes of cancer education to enlarge the knowledge of what can be done in this field. It is also recommended that there should be further facilities for educating physicians and medical students in the early recognition of cancer.

NORWAY

Studies of the Coagulation of Blood.—Last March, at the University of Oslo, Dr. Knut Aas successfully defended his thesis "Investigations of the Coagulation of Blood, with Special Reference to Proconvertin and Convertin." With the help of funds put at his disposal by certain corporations, he worked since the summer of 1950 on experimental investigations of the coagulation of blood at the coagulation laboratory of the medical department A of the Rikshospital. This thesis, which also includes a detailed account of a patient treated in the medical department A and in whom curious features throwing new light on the coagulation of blood were manifest, may be described as an important link in the chain of coagulation studies conducted by the Owren team at the Rikshospital. It will be recalled that Owren's discovery, in 1943, of factor V in the processes of coagulation was followed, in 1947, by his discovery of, what he called at this time, cofactor V. Since then these two factors have come to be known as proaccelerin and proconvertin respectively. In his thesis, Dr. Aas reviews the investigations that since 1943 have been undertaken in connection with the conversion of prothrombin to thrombin, and he explains the working hypotheses from which his own research started. He confirms Owren's hypothesis concerning the nature of proconvertin and convertin, and he suggests that the discrepancy between the results obtained by the one and the two stage methods of prothrombin determination may be explained by recent observations concerning the proconvertin-convertin and the proaccelerin-accelerin systems. The detailed account Aas gives of the technique of the quantitative determination of the clotting factors should prove helpful to workers in other parts of the world.

In a recent appeal to the general public, Owren drew attention to the need for support of organized research in Norway in the faulty coagulation of blood including thrombosis. This group of diseases has, in his opinion, caused more deaths after the age of 50 than any other morbid process. Since 1948, he has developed a cautious system of bishydroxycoumarin (Dicumarol) treatment, aiming at an accurate dosage graduated to avoid the extremes of too timid or too heroic methods. As a result of this work, he no longer gives large doses at intervals of some days; he has determined the exact daily dose of the drug that each patient needs to achieve a normal coagulation level. This dosage is based on exact methods for the estimation of prothrombin and proconvertin. Once the proper dose for each patient has been found, bishydroxycoumarin treatment can be continued indefinitely, with a blood examination only every fortnight or three weeks. Owren's patients are thus enabled to continue treatment after discharge from hospital and need only to send him samples of their blood by mail from time to time. Dr. Owren has worked on these problems since January, 1949, and now has several patients who have received constant bishydroxycoumarin treatment for up to four years. Dr. Owren is encouraged by the results he has achieved, for many of his patients with coronary disease have been enabled to return to work because of this prophylactic treatment.

Standardization of Serologic Tests for Syphilis.—At the Gade Institute in Bergen, the routine serologic testing for syphilis includes Wassermann tests, with three different antigens and three different flocculation tests; Kahn's standard reaction; Meinicke's "Klärung's" reaction, and venereal disease routine laboratory test. The technique of each test differs so in various parts of the world, and even within the boundaries of Scandinavia, that there is at present little hope of a fair comparison of the results of each. Commenting on this situation, Prof. T. Vogelsang of the Gade Institute suggests, in *Nordisk medicin* for July 2, 1953, that it would be possible to adopt international standard methods the employment of which would be obligatory. In 1947, a comparison of the Wassermann test as employed in both Copenhagen and Bergen showed that the sensitivity of this test in Bergen was considerably greater than in Copenhagen. On the other hand, this test seemed to yield a greater number of nonspecific reactions in Bergen. While the Copenhagen antigen contained only 0.26% cholesterol, the corresponding figure for the Bergen antigen was 1%, a figure subsequently reduced to 0.8% with a view to rendering the test more specific although somewhat less sensitive.

Professor Vogelsang's appeal for international standardization in this field is supported by the evidence he presents of the growing importance of testing for syphilis as illustrated by statistics from his own laboratory. In its first year (1912), the Gade Institute dealt with only 102 samples of blood for Wassermann testing. At the outbreak of World War II, the corresponding annual number was between 5,000 and 6,000, and at the present time some 18,000 samples of blood are dealt with yearly. The samples of cerebrospinal fluid have shown a parallel rise, with only 500 to 600 a year before the war as compared with some 1,300 a year at the present time. At one time it was chiefly because of clinically suspected syphilis that samples of blood were sent to the institute, whereas, at the present time, testing for syphilis has become a matter of routine now that serologic tests are compulsory for pregnant women. There are also the would-be emigrants and other groups requiring certificates of freedom from syphilis. A comparison of the figures for the first half of 1939 with the first half of 1952 shows that the percentage of syphilitic serums has fallen, but the actual number of such serums has risen from 646 out of 3,331 in the first period to 881 out of 7,468 in the second period. Professor Vogelsang's description of the change since World War II in the treatment of syphilis as revolutionary is to a great extent a tribute to penicillin as a substitute for arsenic and heavy metals.

Influence of Age, Marriage, and Other Factors on Breast Cancer.—The Norwegian Radium Hospital has dealt for so long with so many cases of cancer that the material now at its disposal is well suited to statistical investigation. Two members of its staff, Selmer Rennaes and Lita Holan, have undertaken a study of the 1,784 women who were treated at this hospital in the period 1932-1944 for cancer of the breast. After the deduction of 236 cases in which information concerning the number of children born to each patient was incomplete, there remained 1,548 patients, approximately half the total number of women suffering from cancer of the breast in Norway in the same period. The breast cancer rate was higher among the unmarried than among the married patients, and between the ages of 50 and 55 the married women showed a fall of the breast cancer rate. For the unmarried women there was a similar fall, but it occurred some 10 years later. Similar observations have been made elsewhere, first in Denmark and later in Switzerland and England. The Norwegian statistics also showed that the breast cancer rate was inversely proportional to the number of children the patients had had. In their comments on this investigation, published in *Nordisk medicin* for July 9, 1953, Rennaes and Holan digress to discuss the action of hormones on experimental animals and human beings. With regard to the latter they point out that the administration of diethylstilbestrol (Stilbofollin) to elderly women may be followed by marked regression of both the primary breast tumor and gland metastases. Also that castration plus testosteronepropionate (Testin) can effect both subjective and objective improvement in young women suffering from breast cancer.

PARIS

Experimental Ethylism.—J. Lhermitte presented before the National Academy of Medicine his work on experimentally produced ethylism. He stressed that it is difficult to evaluate precisely the pathological role of ethylism in human organism. Even when a series of changes in organs are observed at autopsy, it is found that they are not due to poisoning by ethyl alcohol only but often to such other affections as malnutrition, vitamin deficiency, syphilis, and tuberculosis. Experiments performed by various authors have resulted in errors, either because the amount of alcohol introduced was inaccurately estimated or because an alimentary unbalance and a deficiency of ingestion and absorption of vitamins was superimposed on ethylism. In his recent experiments the author succeeded in avoiding these errors. He introduced diluted absinthe by means of a special apparatus, directly into the digestive canal of female rabbits that were being fed an abundant and varied diet. The test lasted from 6 to 8 months, after which autopsy showed that the gastric mucosa had thickened and gave evidence of interstitial gastritis in the prepyloric region. The ulcerations reported by the other authors were never observed. The liver had the appearance of a cardiac liver when the animal died within the first months, but, when poisoning had been present for a longer period, a cirrhosis of the Laennec type occurred, which was identified by the proliferation of portal connective tissue and alterations of portal blood vessels, some of which showed complete thrombosis. A fatty degeneration of the parenchyma was also often observed. A female rabbit subjected to poisoning with ethyl alcohol for over six months had eight stillborn offspring with tegumental dystrophy. Only one of the offspring survived, and autopsy revealed a cirrhosis of the Laennec type. This finding is new and shows that ethylism has an action not only on the liver of the adult but also on that of the fetus. As regards the nervous system, the effect is different on the spinal cord and the cerebellum on the one hand and on the peripheral nerves on the other. In the spinal cord, anterior radicular cells are deeply damaged. In the first stage chromolysis, karyolysis, edema, pus, and complete cytolysis appear; in the last stage the disappearance of protoplasm is complete. At the same time, a reaction of the microglial, perineuronic elements produces images of "neuronophagy." On the other hand, there are no vascular or meningeal lesions. In the cerebellum, lesions restricted to the Purkinje's cells are noted, and there is a form of degeneration similar to that found in the spinal cord, but the constituent elements of the cerebral cortex are undamaged. In contrast to these deep changes, no vascular or inflammatory reaction is noted in the peripheral nervous system.

Labyrinthic Hypotension.—Vertigo due to hypertensive disorders of the labyrinthic fluids is well known. In the *Journal de Médecine de Lyon,* 1952, pp. 821-826, R. Mayoux described a hypotensive origin of this disorder. The syndrome in these cases is generally buzzing, vertigo, and deafness. Hypotensive vertigo is observed especially in young persons in whom arteriosclerosis is precluded; but, in these same patients, labyrinthic hypotension and hypertension may alternate. As to the mechanism of this labyrinthic hypotension, after having observed 21 patients, the author admits the existence of a vasomotor unbalance, inducing a diminution of pressure in the internal auditory artery and, then, a fall of pressure in the vascular stria of the cochlea secreting the endolymphatic fluid. Among 21 patients showing syndromes of labyrinthic hypotension, the author observed 14 subjects in whom the pressure in the central artery of the retina was very low. The author stresses that the internal auditory artery and the central artery of the retina belong to the cerebral circulatory system.

For treatment he recommends the intravenous injection of distilled water. He obtained spectacular and immediate results and, in the rare cases of relapse, further treatment with distilled water brought about complete recovery.

Hereditary Factors in Development of Cancer.—P. F. Denoix, M. P. Schutzenberger, and G. Denoix studied 3,300 case histories gathered in the anticancer centers of France, to determine the influence of heredity on the development of cancer. In each case the site of the cancer as well as the existence of a cancer in the patient's brothers, sisters, parents, and grandparents was noted. In a study published in the *Bulletin de l'Institut National d'Hygiène,* the authors drew certain conclusions from their investigations. There is a familial tendency toward development of cancer in specific sites. There appears to be a certain hereditary predisposition in given groups to cancers of the upper respiratory-digestive tract, uterus, and breasts. The proportion of patients whose parents had cancer was 10 to 15% for all sites; it is notably higher than that of grandparents. Moreover, there is a certain matroclinous tendency in female patients, i. e., the proportion of cancers in the sisters, mothers, and grandmothers of patients is larger than among male members of their families. More maternal grandmothers of cancerous patients than paternal grandmothers also had cancers. The authors intend pursuing their investigations on a larger scale.

Antigenic Variations of Salmonella Typhosa.—A. Jude and P. Nicolle reported initial results of their work on antigenic variations in Salmonella typhosa cultivated at different temperatures to the National Academy of Medicine. After incubation at 37 C Salmonella typhosa is very rich in antigen Vi. Therefore it is well protected against humoral antibodies and phagocytosis. Conversely, at a temperature of 41 C and 18 C the production of antigen Vi is much diminished but the culture is very rich in antigen O, which makes it very toxic for laboratory animals. These experimental studies and clinical observations of typhoid patients led the authors to believe there is a relation between the symptoms of the disease and the modifications of the bacillus in the course of the disease.

Diabetes.—In the March-April issue of the journal *Le Diabète,* Darnaud, Ferret, Denard, Moreau, Voisin, and Commanay reported on 2,000 cases of glucosuria. Four per cent of these patients had renal diabetes, among whom were some who were treated with insulin because their condition was not recognized. A direct cause of diabetes was found in only 2% of the cases, with the commonest associated condition being exophthalmic goiter (Basedouis disease). In 30% of cases there was a familial history of the disease. In 10% of cases the patients were children, and more than 50% of the patients were over 40 to 50 years of age. A characteristic fact has been stressed by the authors: 87% of diabetics under 40 years of age have acidosic diabetes; conversely, the majority of patients over 40 have been obese in the past and are not acidosic. As to complications, polyneuritis occur in 15% of the patients, tuberculosis in less than 2%, and degenerative vascular complications in over 20%. Vascular complications are commoner in long standing diabetes.

Preventoriums for School Children.—At a meeting of the National Academy of Medicine, Fourestier M. David and R. Huguet reported the results of a new experiment with school children. During the winter of 1953, 31 children of a municipal school, from 12 to 13 years of age, were sent with their teachers to a winter station in Savoie at an altitude of 1,400 m., where they lived in a chalet especially equipped for them. During the month one-half of the time was devoted to instruction and the other to sports, with classes in the morning, sports in the afternoon, and a long siesta afterwards.

Remarkable results were noted; from the physical point of view, remarkable improvement occurred and learning productivity increased greatly. The authors believe this new system has a better preventive action and ought to be systematically organized for whole classes in order to benefit children with latent deficiencies as well as those in good health.

CORRESPONDENCE

CORONARY DISEASE AMONG SOLDIERS

To the Editor:—The interesting report by Enos, Holmes, and Beyer (Coronary Disease Among United States Soldiers Killed in Action in Korea, *J. A. M. A.* **152:**1090 [July 18] 1953) calls for comment. On its face value it is very alarming to find that, in 300 autopsies of young soldiers killed in action or in accidents who showed no clinical evidence of coronary disease during life, 77.3% had some gross evidence of coronary arteriosclerosis on postmortem examination. The average age was given as 22.1 years. The authors' statements leave us with the impression that upward of 77% of the youth in our country have coronary disease; this would, of course, be a frightening state. If we look over the few figures presented, however, we find that the ages were apparently obtained in only 200 cases, the youngest being 18 years and the oldest 48 years, with an average of 21.1 years. In 98 cases, the authors state that no age was recorded "except that the oldest was 33 years." If no age was recorded, how can one tell that the oldest was 33 years?

An analysis of the interesting coronary pathology they observed reveals that, in the entire series of 300 cases, no coronary disease was found in about 23% and "fibrous" thickening or streaking of the coronaries with insignificant luminal narrowing occurred in 35%; this makes a total of 58% free, or practically free, from coronary disease. In the remaining cases, 13.3% showed only an estimated 10% and in 6.3% only 20% of luminal narrowing, which would bring up the total number of cases to 78% with no coronary disease, insignificant changes, or comparatively trivial changes. Luminal narrowing in a degree of 30% or more occurred in only about 19% of cases, and in 3% complete occlusion of one or more vessels was observed. Clinically important coronary disease, therefore, occurred only in about 22% of the cases. Inasmuch as the authors did not correlate the various degrees of coronary disease observed with the ages of the patients, we can not tell whether these 22% of cases comprise the younger or older ages. My guess would be that they include mostly the older ages.

It would be of great value if further studies were continued by these authors and other groups who are able to obtain autopsy material in accidental deaths and an attempt were made to correlate the degree of any coronary pathology found with the ages of the patients. Only in that way can we ultimately get a true analysis of the incidence of asymptomatic coronary disease at various ages. There have been to date several recorded series of cases by various authors in the literature correlating age with the degree of coronary disease. That of Yater and co-workers (Comparison of Clinical and Pathologic Aspects of Coronary Artery Disease in Men of Various Age Groups: A Study of 950 Autopsied Cases from the Armed Forces Institute of Pathology, *Ann. Int. Med.* **34:**352, 1951) comprises the largest series. In all these, however, death was attributable to coronary disease not to accidental causes.

RECEPTION OF PATIENT

To the Editor:—I wonder if we always "see ourselves as others see us." I am a physician in Ohio. I recently received the following letter from my daughter in a distant city.

"This A. M. at 8:30 I kept an appointment made two weeks ago with an 'eye-doctor.' Had to wait 45 minutes, endure his off hand examination made while talking animatedly with his nurse about golf arrangements or something and paid him ten dollars when he finished deciding my eyes are all right and my headache 'emotional,' probably. It certainly can't be difficult for a doctor to assume an attitude of concern—that is what creates confidence."

Name withheld on request.

BUREAU OF INVESTIGATION

JACOB S. SCHIRMER

Investigation Report of Arkansas Attorney General

The Honorable Tom Gentry, Attorney General for the State of Arkansas, has filed a complaint in the circuit court of Clay County, Ark., wherein Jacob Sass Schirmer of Corning is named defendant. The attorney general demands that Schirmer show by what legal right he is exercising the franchise and privilege of the practice of medicine in Arkansas and prays the court to enter a judgment preventing and forbidding Schirmer from practicing medicine.

Attached to the complaint is the report of an investigation of Schirmer's present and past activities. Schirmer has been in the forefront of the promotion of the Koch "Glyoxylide." He was the first president of a group calling itself the "American Association of Physicians," which published at intervals a journal devoted to the promotion of the Koch nostrums among physicians and cultists who use the material. More recently he has been a "Research Associate" in the Lincoln treatment.

The Journal publishes, in its entirety, the report of the special assistant attorney general who was appointed to investigate Schirmer's license and his so-called practice. This is done to enable its readers to learn what is behind a medical quack. It is hoped that this report will serve as a guide to those in medicine who have to do with the licensing and qualifications of doctors and as an example of the painstaking thoroughness required of those whose duty it is to expose quacks.

It may be observed by some that this is a unique situation. Nonetheless, there are persons who pose as doctors of medicine who are neither legally nor morally entitled to administer to the needs of the communities in which they practice or to the gullible public generally which responds to their advertising and their promotional activities. The investigational report on which the complaint was based follows.

"I submit here the report of the investigation of Jacob Sass Schirmer of Corning, Arkansas. No doubt a word of explanation as to the length of the report and as to the wide scope of the investigation is appropriate. The complicated and complex method used by the subject in reaching his objective, a license to practice eclectic medicine in the State of Arkansas, necessitated a complete review of his activities over a period of nearly twenty years. During this time he pursued this objective from Georgia to Missouri to Arkansas to Connecticut, back to Arkansas then to Georgia again, and from there to Indiana and then back to Arkansas. It is incredible that Schirmer could have obtained a license to practice medicine in the manner he did and then could continue to practice in the manner he has for the length of time which has elapsed without the fact that he originally obtained that license by deceit being brought to light. It is also incredible that there would be allowed to exist in the enlightened state of Arkansas an institution operated such as Schirmer's so-called research hospital. Of this hospital the State Special Investigator reported, 'The hospital does not treat any local patients; even though it might be an emergency case they would not accept them. No local doctors practice in this hospital. The turn-over of doctors practicing in the hospital seems to be quite large. A doctor may work in this hospital from two weeks to six months and then be gone. They seldom leave a forwarding address for mail at the post office. They do not mix and mingle with the citizens of the town socially, do not attend their churches, and I was told by two or three citizens that the hospital specializes in the treatment of cancer, tuberculosis and leukemia; that apparently the same treatment is given in all cases, that being some kind of an inhalant which is breathed through the nose. I understand these treatments are quite expensive, sometimes as much as $400.00 per week for a patient, and that the hospital does not accept checks; that in various instances the patient or some of his family goes to the local bank and draws checks on their respective bank back at their home in order to pay the hospital cash. Some of the people I talked to said the hospital is operated very strangely and that the people of Corning don't know what is going on, as very few of them have ever visited in the hospital.'

"A possible explanation of the failure of the responsible citizenry of Arkansas to act against Schirmer is that since 1934 he has held what appears upon the surface to be a valid license to practice eclectic medicine. Only a thorough and painstaking search of the records of several states brought to light positive evidence that he was not entitled to this license and had obtained it after years of cunning maneuvering and in an extremely ingenious manner. May I observe in passing that ordinarily when an individual has been allowed to practice as long as Schirmer, even though he does not possess the necessary qualifications for a medical license, there is a natural disinclination to disturb him in his later years. This is not true, however, when that individual, given a feeling of security by the passage of time, embarks upon a career or a course of action which endangers the public welfare and becomes a menace to mankind. I find that Schirmer is considered by responsible authorities as one of the most notorious cancer-cure quacks of the day. He has reaped and is reaping a harvest of dollars at the expense of those poor and unfortunate persons who are afflicted with incurable diseases and who will turn to anyone who will raise false hopes in them for a fee, the size of the fee is immaterial when life itself is sought to be prolonged. Any so-called doctor who decides to assume this position is entitled to expect that both his professional qualifications and his moral character will be carefully scrutinized by those public officials to whom the duty of protecting the public has been entrusted. He should be willing to disclose his life's history and activities so that the public itself may judge whether he is honest and sincere. Those who cry 'persecution' and who seek to draw some religious curtain between them and the cold light of public scrutiny are but revealing their inability to stand examination.

"In order to understand and to appreciate the reasons for Schirmer's many movements and circuitous action, it is essential that one keep in mind the requirement of the Arkansas statutes that the applicant for a medical license be a graduate of a 'reputable medical school' and that it was some few years after the enactment of this statute that the Arkansas Supreme Court interpreted that provision to mean a school which had a four-year course of study and a curriculum as good as or equal to the better class of medical schools in the United States. A number of licenses were issued between the date of the adoption of that law and the Supreme Court opinion which were based upon diplomas from so-called medical schools which were schools in name only.

"How such a situation could arise is an interesting historical story. At the turn of the century medical men had been divided in opinion as to whether allopathic or eclectic medicine was to be preferred. Eclectic colleges of medicine were just as reputable and prominent as allopathic colleges. There were undoubtedly good methods in both theories and it was inevitable that sooner or later the good in both would be combined into one theory of medicine. Since both had equal standards, states enacted laws giving each equal privileges and standing. Arkansas' 1903 Medical Act created separate licensing boards but provided that the same laws should apply to both. As I have said previously, it was inevitable that the two theories would eventually merge or that one would take over the other. In the early 1900's the eclectic colleges began moving in with the allopathic colleges. This movement left a peculiar situation in some states. Here were laws permitting eclectic boards to issue perfectly valid licenses to practice medicine, and nobody to take advantage of them. It didn't take long for some enterprising and unscrupulous individuals to cash in on the market before the states could adopt legislation to plug the holes left in their medical licensing laws. Under most state laws, if an individual had a diploma from an eclectic medical college, he was eligible for a medical license. Quickly abandoned and dormant eclectic schools were reopened under private ownership. Thus for a brief period flourished the diploma mill. All that was necessary was to pay the tuition fee; a diploma was forthcoming.

"But it was essential that there be a companion-in-arms with these mills. Eclectic Licensing Boards must be found who would cooperate in the fraud on the public. In a few states unscrupulous men seized control of eclectic licensing boards. Licenses were sold 'en masse' and so-called 'graduates' from the diploma mills flocked to these states for licenses. Thousands were ushered into the practice of medicine without qualification. A national scandal was in the making. The reputable eclectic physicians and colleges were helpless. (Reciprocity is a necessity in professional fields.) The reputable could not afford to abolish reciprocity, nor were they able to stem the tide of fraud, deceit and graft in their field, and as a consequence many fine, qualified eclectic physicians have been forced to suffer the embarrassment and shame of having quacks and charlatans hold themselves out as true eclectic physicians.

"The American Medical Association, in an effort to keep up with the swelling tide of physicians, set up a record bureau and published a listing of all physicians, whether allopathic, eclectic, homeopathic, etc. This became the only official record of all physicians, and listing was considered a necessity even by the quacks. There was no charge for the listing; all boards regularly reported the names of those to whom licenses had been granted and those who failed examinations. Regularly data cards were sent to all physicians listed, and an up-to-date record was sought to be kept on all. No effort was made to grade the physician or to credit or discredit him. The statements made by him were accepted as true and entered upon the card.

"One of the most prominent and enterprising gentlemen to reap the golden harvest of the diploma mill was Date R. Alexander, who operated the notorious Kansas City diploma mill and was eventually convicted and sentenced to the federal penitentiary in connection with his fraudulent issuance and sale of medical diplomas from his Kansas City College of Medicine and Surgery. For a while his 'college' was the mecca for the person who wanted to be a doctor but who didn't have the time or energy to prepare himself through attendance at a reputable medical college. Working with Alexander were several state eclectic licensing boards, the most notorious being that of Connecticut. Also working with him was the then Secretary of the Arkansas board, Dr. C. E. Laws, who was later convicted and sentenced to the federal penitentiary along with Alexander. It does not appear that the remainder of the Arkansas board was in on the deal with Alexander and Laws, but possibly should be charged with considerable negligence and inattention to duty, as will be subsequently seen. Alexander had a protege who was a product of this maelstrom of the golden age of quackery. His name was Jacob Sass Schirmer, whom it took twenty years to obtain a license by the use of his wits, and who was destined to become a protege of the infamous Koch and now the leading exponent of the Lincoln inhalant cancer and leukemia cure.

"Schirmer was born in Charleston, S. C., but the exact date seems to be questionable. He claimed to have been born in 1884 on his data card furnished the A. M. A. in 1922. In his application to the Connecticut Licensing Board in 1920 he gave his birth date as 1888, and later, in 1948, he gave his birth date as 1892 on a subsequent data card sent him by the A. M. A. It is somewhat amusing to examine the records of the A. M. A. on Schirmer. He gave such conflicting data on his various reports to the A. M. A. and to the other bodies to whom he furnished a history that the record section had three separate and distinct personnel cards on him. He claimed to have graduated from high school at Ashland High School, Ashland, Mass., in 1903. (I have in my possession a certificate from the Superintendent of Schools of Ashland, Mass., that a search of the records of that school from 1897 through 1908 failed to reveal the name of Jacob Sass Schirmer or Jacob S. Schirmer.) He became a motion picture machine operator at Atlanta, Georgia, where his father was a chiropractor specializing in treatment of chronic nervous diseases. He claims to have attended the Georgia College of Eclectic Medicine and Surgery from 1908 until 1913, but this claim is not substantiated by the records of the college. I have examined the lists of students published by that school for the periods mentioned, and his name does not appear for any of the years claimed. (It is also reasonable to assume that were this claim true, it would have been unnecessary for him to go through all the later maneuvering he performed to get a license in Arkansas.) I have also interviewed persons who knew him at Atlanta during this period who have stated to me that he was a motion picture machine operator and made no claim to being a physician.

"He now claims to have had a residency in the private hospital of one Dr. W. B. Lingo, a notorious cancer-cure quack of that age. Lingo was also 'dean' of the Southern School of Medicine and Surgery at Atlanta. The Atlanta *Banner* on Oct. 13, 1916, carried a full story of the investigation by the Georgia Board of Medical Examiners of the fraudulent issuance of diplomas by Dr. Lingo's college and the fraudulent issuance of eclectic medical licenses by one Dr. C. W. Miller, who was secretary of the Eclectic Licensing Board. It is interesting to observe that the legislature of Georgia abolished the Georgia Eclectic Licensing Board in July of 1913. Thereafter a number of licenses signed by Miller and dated May and June 1913 appeared in Georgia. The news article in the *Banner* reports parts of this investigation in this manner: 'Dr. W. B. Lingo was dean of the college. It developed that the board might prosecute Dr. Lingo on charges of perjury. It was alleged that he had attended a medical college in Baltimore, had gone to Nevada and obtained a license under the law which required only registration and then returned to Georgia and had been given a reciprocal license. The testimony relating to Drs. Tallent and Goodson was that they had attended the Georgia College of Eclectic Medicine and Surgery in the spring of 1916. They recorded licenses dated June 1913. It was brought out that Dr. C. W. Miller, a member of the eclectic board the latter part of September and October 1913, two months after the board had been abolished by the legislature, issued 28 to 30 licenses. Dr. Nolan, secretary, asserted that there is someone in the state making a practice of issuing these licenses and dating them back. The licenses held by several doctors which were revoked Thursday are alleged to have been dated back.'

"This above story is pertinent to the present investigation because in 1917 Schirmer filed a purported Georgia eclectic medical license at Savannah, Chatham County, Georgia, which is some considerable distance from Atlanta where he was living. This purported license is of interest in that it is dated May 3, 1913, and is signed by C. W. Miller. There is no record of Schirmer ever having lived in Savannah, and the license was never recorded at Atlanta, where Schirmer lived. I have in my possession affidavits from the secretaries of the Georgia State Medical Boards that Schimer was never issued any license to practice medicine by any Georgia board, according to the records of the boards. No report of the issuance of such a license was ever made to the A. M. A. record section, nor was any report ever made that Schirmer had applied for or had taken an examination for a Georgia license. Apparently this license was too hot for even Schirmer to handle, because he has never used it as a basis for reciprocal license claims. (His later actions demonstrate that he had no confidence in this so-called license.)

"About March 1917 Schirmer's name appears on the list of applicants for matriculation to the College of Physicians and Surgeons at Boston, Massachusetts. This college published quarterly a list of the applicants for matriculation and a list of the students in attendance. Schirmer's name appears first in the Quarterly Vol. 38, #2, which is for the spring of 1917. He does not appear in any of the subsequent quarterly listings until a year later, in Quarterly Vol. 39, #2, which is for the spring of 1918. Again he does not appear in any of the subsequent quarterly listings until Quarterly Vol. 41, #3, which was for June 1919, when he was again listed as an applicant for matriculation. Why he never followed through on his application is probably explained by the language in the report of the Hartford, Connecticut, Grand Jury of 1924, which states in part: 'The Grand Jury caused an investigation to be made of the College of Physicians and Surgeons of Boston; the Dean gave information freely, stating most emphatically that the institution was *not* an eclectic institution and never had been, and the Grand Jury finds as a fact that such is the case.'

"Schirmer next appears in Kansas City, Missouri, during the early part of 1920, where he was attending the Kansas City College of Medicine and Surgery, operated by the notorious Dr. Alexander. Schirmer now claims to have attended this so-called college for a 'post-graduate' course in medicine, but, as will be seen, during his later attempts to obtain a license from various eclectic boards, he listed himself as a graduate of the Kansas City College of Medicine and Surgery, that is, until that school was shown to have been pure vehicle for fraud by Dr. Alexander.

"On May 11, 1920, Schirmer came to Arkansas and made application for license to the Arkansas Eclectic Medical Board. He took the examination and failed, receiving a grade of 57 6/12 per cent. I have in my possession a photostatic copy of the minutes of the Arkansas Electic Medical Board of that day, in the handwriting of the secretary, showing Schirmer's failure and also the official report of 'Examination for License to Practice Medicine' furnished the Council on Medical Education of the American Medical Association by the secretary of the Arkansas Eclectic Medical Board, showing that Jacob S. Schirmer failed the examination for license on May 11 and 12, 1920.

"Schirmer immediately followed the mass movement to Connecticut, and on July 13, 1920, allegedly took an examination before the Connecticut Board of Eclectic Examiners. His good moral character and professional standing being vouched for by Dr. Date R. Alexander, Schirmer listed himself in his application before this board, of which I have a photostatic copy, as being a graduate of the Kansas City College of Medicine and Surgery. Thereafter, having obtained a license from a state with which Arkansas had a reciprocal agreement, Schirmer returned to Arkansas, and on May 11, 1921, received a license from Arkansas, by reciprocity with Connecticut. The granting of this reciprocal license was duly reported on the regular forms by the secretary of the Arkansas Eclectic Medical Board immediately thereafter. I have a certified copy of this report, signed by the secretary and in the handwriting of the secretary.

"Schirmer then moved to Urbanette, Arkansas. In due time the secretary of the Connecticut Board reported to the Council on Medical Education that Jacob S. Schirmer of Urbanette, Arkansas, a graduate of the Kansas City College of Medicine and Surgery, had been granted a license to practice medicine by the Connecticut Eclectic Board of Medical Examiners. Notation was accordingly made on the personal data card of Schirmer by the A. M. A.

"Schirmer practiced in Urbanette, having filed his license for record with the County Clerk of Carroll County, as required by the statutes of Arkansas (Act 22 of 1903). This seems to be the fatal error committed by Schirmer in his entire plan of campaign, since the license is still on record and shows plainly that it was issued by reciprocity with Connecticut on May 11, 1921. I have in my possession a certified copy of this license, showing that it was granted upon reciprocity with Connecticut.

"On the first Tuesday of March 1924, the Grand Jury in the County of Hartford, State of Connecticut, filed a report which was due to electrify the medical profession of the United States and which was to cause a radical decrease in the diploma mills of this country. Connecticut apparently had tired of being the happy hunting grounds for all those who could obtain a diploma from diploma mills. The report of the Connecticut Grand Jury reflects that a wide and extensive investigation was made of a number of so-called eclectic 'colleges,' among which was the Kansas City College of Medicine and Surgery. The following is a direct quotation from the report of the Grand Jury of the investigation of this so-called college:

" 'The Grand Jury made inquiry as to the equipment, teaching staff and curriculum of the Kansas City College of Medicine and Surgery. We, the Grand Jury, find that many persons have been admitted to examinations held by the Connecticut Board of Eclectic Examiners by virtue of possession of diplomas from the Kansas City College of Medicine and Surgery, and hold licenses to practice medicine in Connecticut based upon examination by certificate of that Board.

" 'The paid teaching staff consists of two men who receive $100.00 a month. The school is owned and operated by Dr. Alexander. There has not been a meeting of the faculty since 1915. There are no persons connected with this college who have any knowledge of educational qualifications or the administering of an educational institution from the standpoint of efficiency. The conditions existing in this college are almost unbelievable. The man who was introduced as the teacher of anatomy is not a doctor. The head of the school said he was enrolled as a student but the records of the school did not bear out this statement. The classes are taught together; there is no attempt to verify the credentials presented by applicants for admission to the college and the entrance requirements are practically nil. The head of the school stated that if a student claims to have passed certain courses of study, he accepts his statement, as it makes no difference to him. Anyone is welcome, and anyone who has the cash to pay is sure to go away with a diploma. Diplomas are issued to applicants at a charge of approximately $200.00 each, and these diplomas are issued for the purpose of giving the holder thereof the opportunity to appear before Eclectic Examining Boards in some states, but principally Connecticut. The dishonorable traffic in diplomas to be used for this purpose was freely admitted by the head of the school, coupled with the statement that hereafter the price would be higher. It was impossible to obtain a medical education in this college—and students knew it and the diplomas were sought and obtained for the purpose of practicing fraud upon the authorities in the State of Connecticut. The persons receiving a license from the State of Connecticut founded upon a Certificate issued by the Eclectic Board as a result of examinations of such persons, as a graduate of this school, were issued because of the fraud and deceit practiced upon authorities in Connecticut.

" 'We, the Grand Jury, find that there was some question at one time as to the St. Louis College of Physicians and Surgeons and that persons went from that college, and from elsewhere, to the Kansas City College of Medicine and Surgery and came away in less than an hour with a diploma from the latter college. So-called doctors examined by the Grand Jury admitted that they never attended courses of study at the Kansas City College of Medicine and Surgery, had spent less than an hour at that institution, and had paid from fifty to three hundred dollars for the diplomas received.

" 'There is a respectable and apparently responsible National Eclectic Association, the officers of which protested to the Connecticut Eclectic Society and warned against examining persons holding diplomas from the colleges above named, characterizing them as frauds and "bastard institutions." Yet, notwithstanding this warning, and the knowledge which the warning would have conveyed to honest, intelligent persons, the Connecticut Eclectic Society, composed in the main of graduates from these fraudulent institutions, voted to place them upon the list of colleges whose graduates would be accepted by the Connecticut Board of Eclectic Examiners for examination.'

"Before the issuance of the report of the Connecticut Grand Jury on February 16, 1924, it had obviously been turned over to the Commissioner of Health of Connecticut, and there had been a considerable upheaval in that state. A new Eclectic Medical Examining Board was appointed and a review made of all licenses which had been granted by the old board. On February 1, 1924, Schirmer was advised by the Commissioner of Health of Connecticut that his Connecticut license had been revoked by the Connecticut Eclectic Medical Examining Board for fraud and deceit as of January 31, 1924. Thus, the roof caved in on Schirmer. His Arkansas license, duly recorded where he was practicing, showed that it was based on reciprocity with Connecticut. His Connecticut license had been revoked for fraud and deceit.

"On February 17, 1924, the newspapers of this area carried the story of the Connecticut investigation and action. The *Arkansas Gazette*, in its Sunday, February 17, 1924 issue, on page 8, carried the story as it pertained to Schirmer. This newspaper pointed out the effect on Schirmer's Arkansas license of the action of the Connecticut Grand Jury and the Connecticut State Board of Health. Schirmer immediately fled from the state. On February 21, 1924, Schirmer addressed a letter to the Commissioner of Health of Connecticut, stating that he wanted to be furnished proof of his fraud and deceit. He begins his letter by saying: 'Your letter under date of February 1 just received.' This letter of Schirmer's is written on stationery of Dr. J. F. Schirmer, 'Chronic Nervous Diseases a Specialty,' Silvey Building, Atlanta, Georgia. It purports to have been written from Urbanette, Arkansas, but it is obvious that if Schirmer had been in Urbanette he would have used his own stationery.

"Schirmer returned to Atlanta, Georgia, and on April 23, 1924, was indicted in Fulton County in Indictment #22104 for practicing medicine without a license. There was no trial, dismissal or conviction of this indictment, but we find that Schirmer went back to operating a motion picture machine. He lived in Atlanta, at 29 East Lake Terrace, making his living as a motion picture machine operator, and, I am informed, manufacturing and selling 'stink bombs' in a laboratory he had in his home. Apparently he ran into difficulty with the owner of the Palace Theater. He employed a man named W. F. Moss to throw a 'stink bomb' in the Palace Theater in August of 1925. On August 16, 1925, the Atlanta *Constitution* carried an article referring to this incident which stated that a panic was created at the motion picture theater, where approximately 400 women and children were sitting in the theater. Schirmer posted a $200.00 bond and disappeared. The police judge, after hearing the testimony, summoned the Chief of Police 'and asked him to use the greatest effort to apprehend Dr. Schirmer and to place his bond at not less than $1,000.00. Chief Jett informed the Court that such orders had already been issued and stated that he would accept no less than $5,000.00.' On August 21, 1925, the Grand Jury of Fulton County, Georgia, indicted Schirmer, one W. F. Moss and one Owen Montgomery in Indictment #24687 for the above action. At the same time Schirmer was indicted in #24686 for making his getaway in a Ford sedan automobile with a license that had been issued for another automobile, to-wit: Hudson coupe. I have in my possession certified copies of all three indictments above set out.

"Schirmer fled from Atlanta, drifting over the country following his trade as a motion picture operator. In 1930 he was living in Whiting, Indiana, and was business agent of Moving Picture Operators Local #133. He appears on the records as one of the officers of the International Alliance Theatrical Stage Employes and Moving Picture Operators as J. S. Schirmer, Business Agent, and was on the Executive Board. I am informed that prior to this time he lived at Oak Park, Illinois, under the name of McCabe, until the heat had subsided.

"In my investigation of Schirmer during his period of residence at Indiana, I was told a most fantastic story which, when checked, proved to be authentic. Schirmer's wife at that time, Marjorie, divorced him and was awarded custody of their small son. Schirmer lived at Hammond, Indiana, and his wife lived at Whiting, Indiana, which is just across the highway. Both of these places are on the outskirts of Chicago and are contiguous with Chicago. The Schirmer boy was kidnapped, and a great and extensive search was made in which Schirmer played a leading part. The boy could not be found, and his mother gave him up for dead. Some sixteen years later the mother learned that Schirmer had brought the boy to Arkansas and had raised him to manhood, 'neglecting' to tell her that her son was not dead, and that he had him in his custody. I insert this story in this report to you because it demonstrates the complete heartlessness of this individual and it illustrates the type of man you will be facing if you decide to stop his racket.

"On October 6, 1933, Schirmer wrote Dr. L. L. Marshall of this city. At that time he lived at 2538 Ridge Avenue, Highland, Indiana, which is also on the outskirts of Chicago. The Arkansas Eclectic Licensing Board had been shaken up in the meantime, and Dr. Marshall had replaced Dr. C. E. Laws as Secretary. Schirmer's stationery read J. S. Schirmer, M.D., Highland, Indiana. Schirmer's letter to Dr. Marshall stated:

" 'I lost the address of the Secretary of the State Association and I would appreciate your sending me his address. I am planning on locating some place in Northern Arkansas, and if you know of any desirable location I would more than appreciate any suggestions you might offer. In 1925 we had a fire destroying all my things in fact just escaping in our scant clothing. I lost my Arkansas License at that time in the fire and I told Dr. Laws about it but never requested a duplicate. Please advise me what steps to take and fee to forward for a duplicate.

" 'With the very kindest regards, I am'

"We next hear from Schirmer on January 7, 1934, when he again writes to Dr. Marshall on stationery which this time reads 'J. S. Schirmer, M.D., 24 One Hundred Sixty-Ninth Street, Hammond, Indiana.' This is a most unusual letter, since it is obviously an offer to Dr. Marshall to assist him in bribing his way into an organization to which he was not entitled to membership. This apparently was Schirmer's method of softening Dr. Marshall or ingratiating himself so that Dr. Marshall would close his eyes and issue Schirmer a license in Arkansas to which he was not entitled under the records. The letter reads:

" 'You will no doubt be surprised in hearing from me, but yesterday I had a long talk with Dr. Limm, Vice-President, Jackson Park Hospital and member of the Credential Board of the College of Surgeons. He asked me to make out an application for F.A.C.S. which I did and so while talking I asked him if he could suggest for membership, one from another state and was advised he could and not only that but he could put it over. So I thought that it might interest you and at the same time be quite a slap at some of our Allopathic Surgeons in Little Rock. If Dr. Limm says he will see it through, one can rely upon his word and he will use every ounce of his power to win his point. I did not know if you were a Fellow of the College but thought if you were not and should want the affiliation that this would be a good time to start the Ball Rolling, and you can rely upon my getting the application into the right hand. If you hear of a good location in Arkansas, I would appreciate any information, as I traveled over the Larger part of the Northern part of the state but could not find just what I wanted.

" 'Trusting you had a very Merry Xmas and 1934 be a successful and Prosperous Year, I am'

"Although Schirmer's stationery stated that he was a practicing physician in Indiana, he was never licensed to practice any branch of the healing arts in the State of Indiana. I have in my possession a letter from the Executive Secretary of the Indiana State Board of Medical Registration and Examination stating that there is no record in Indiana 'of anyone by the name of Jacob Sass Schirmer ever having a license to practice any branch of the healing arts in the State of Indiana.'

"Dr. Marshall was not the type man Schirmer had hoped. The records reflect that he did not seek to avail himself of Schirmer's fraudulent offer. Instead, we find that on November 16, 1934, ten months after Schirmer's second letter to him, Schirmer furnished an affidavit to Dr. Marshall which read as follows:

" 'I, Jacob S. Schirmer, M.D., of lawful age being duly sworn deposes and says:

" 'I took a written examination before the Eclectic State Medical Board and was granted a certificate dated November 10, 1920. I further state that in November 1925 my license was destroyed by fire. I am making this affidavit for the purpose of obtaining another license.'

"It should be remembered that Dr. Marshall was well aware of the investigation being carried on over the fraudulent issuance of licenses. He was a reputable physician practicing in Little Rock, and for his own protection, he attached his signed and certified statement to Schirmer's affidavit which read as follows:

"'Upon receipt of this affidavit one of our regular form licenses, signed by all of the present Board Members, was issued. In the blank space originally intended for the word "Examination" or "Reciprocity" to be written—the word "Upon" was struck out and in this space was printed—"IN LIEU OF LOST CERTIFICATE GRANTED UPON WRITTEN EXAMINATION. Nov. 10, 1920." Sent by registered mail to him at Corning, Arkansas, this date, December 14, 1934.'

"May I call to your attention the fact that Dr. Marshall had in his possession the records and minutes of the Arkansas Eclectic Board which would have reflected that Schirmer was issued his license on written examination on November 9th or 10th, 1920, had the statements made in Schirmer's affidavit been true. What then prompted Dr. Marshall's unusual action in placing his signed statement as to why he issued Schirmer's license in the records of the Board? The answer is obvious. An examination of the records of the Eclectic Board reflects that Schirmer's statement was untrue, and that he did not take an examination on the 9th or 10th of November 1920, nor had he been granted a license by that board at that time.

"The minutes of the Arkansas Eclectic Medical Board, written entirely in the handwriting of the Secretary and attested by the President, Dr. Jackson, show that eight individuals took the examination for eclectic medical licenses from this Board on November 9 and 10, 1920, and that Schirmer was not one of the eight. His name does not appear in these minutes at any time or at any place. Also, forming positive proof that Schirmer's statement in his affidavit to Dr. Marshall was fraudulent and deceitful, the report of the Arkansas Eclectic Medical Board to the American Medical Association, signed by the Secretary of the Board as of that date, of which I have a photostatic copy, shows that Schirmer was not one of those taking the examination. There is a very interesting bit of information contained in the minutes of the November 9 and 10, 1920, meeting of the Eclectic Medical Board. I quote: 'Motion by Dr. C. E. Spann that this Board establish reciprocal relations with the Eclectic Board of Connecticut, and that the Secretary extend to the Secretary of the Connecticut Board a proposal that a mutual exchange of licenses between the two boards. Carried and so ordered.' This explains why Schirmer was forced to wait until the spring meeting of the Arkansas Eclectic Board in 1921 to get his license in Arkansas by reciprocity. His later revoked Connecticut license had been issued August 5, 1920, and he could have received a license by reciprocity at the November 9 and 10, 1920, meeting of the Arkansas Board, except for the fact that there had been no reciprocal agreement between Connecticut and Arkansas. After that reciprocal agreement was entered into, Schirmer obtained his Arkansas license by reciprocity with Connecticut.

"Having obtained a license by use of an affidavit not substantiated by the records, and issued solely upon his unsupported statement, Schirmer moved to Corning, Arkansas, and began the practice of medicine. Apparently his practice in the beginning at Corning was not as lucrative as his later 'cancer and leukemia cure' practice, because on January 10, 1938, Schirmer filed a petition in bankruptcy in Case #2002. Schirmer listed his assets as office equipment valued at $100.00 and one set of instruments at $25.00. Schirmer listed no real estate. On February 4, 1938, Hon. Max B. Reid, a capable and competent attorney of Blytheville, Arkansas, was appointed as attorney for the trustee in bankruptcy to pursue assets thought to be held by Schirmer and fraudulently withheld in bankruptcy. In the bankruptcy records we found a claim based upon credit extended to Schirmer on a credit application made by him wherein he stated that he had been a practicing physician 'at Chicago, Illinois, for ten years.' The records reflect that notwithstanding Schirmer's sworn statement that the only assets he had were his office equipment and instruments and approximately $1,000.00 debts owed him, after several hearings at which he was vigorously cross-examined by Mr. Reid, Schirmer produced approximately $6,000.00 in cash and settled with his creditors.

"Schirmer's bankruptcy is of special interest, viewed in the light of the recent announcement that he had transferred his research hospital to a church and that the hospital was valued at $400,000.00. *The question immediately arises* as to how a physician in a small town can accumulate this kind of wealth in such a relatively short period, especially when that very physician had gone bankrupt in his first four years of practice in this same town. The answer is even more fantastic and bizarre than Schirmer's earlier activities. After clearing his slate of the debts and losses of his beginning practice, Schirmer associated himself with and became one of the leading exponents of the mythical cancer cure originated by one William F. Koch of Detroit. Koch, one of the most notorious quacks and frauds of the modern era, was the subject of an article appearing in the *Commercial Appeal* of Memphis, Tennessee, on Monday, February 20, 1950. I commend that article to your reading for a full disclosure of the associates of Koch and his satellite, Jacob S. Schirmer. The *Commercial Appeal* says:

"'It's an interesting assortment of quacks, anti-Semitics, Fascists, rabble-rousers and low-rated ministers that has gathered around Dr. William Frederick Koch to peddle and propagandize his "cure" for cancer known as "glyoxylide," which Government chemists says is indistinguishable from distilled water.'

"Let us examine Koch's associates, that is, the principal figures in Koch's movement. Koch himself announced a cancer cure a year after graduating from a medical college, the Detroit College of Medicine and Surgery. He immediately began a wide advertising campaign to sell his product which he called 'glyoxylide.' He formed the Koch Cancer Foundation, gathering around him a collection of known quacks and medical frauds. He then formed Koch Laboratories, Inc., which owned and manufactured Koch's so-called 'glyoxylide.' When Koch's claims gave him national notoriety, he immediately joined forces with the notorious Gerald B. Winrod, an alleged minister, Rev. Sam Swain and an undertaker who was a friend of Winrod. All had many times been openly branded as out-and-out Fascists. Indeed, Winrod was directly linked with the Silver Shirts in a 1940 report of the House Un-American Activities Committee. These individuals, following the path of the quacks for ages, changed the organization from Koch Laboratories, Inc., and sought to hide behind religious protection. They named their corporation the Christian Medical Research League of Detroit. Winrod, who immediately made claims publicly that Koch was 'the founder of a science which will in all probability revolutionize the medical profession,' was the editor of the Defender Magazine, a known anti-Semitic publication which, cloaked by a religious front, became the chief advertising medium for the Koch gang (of which Schirmer was one of the principal exponents), using his hospital as the chief testing ground. The Koch group set up in Detroit what they called 'The Lutheran Research Society,' which the Lutheran Church immediately branded as having no connection whatever with any legitimate Lutheran enterprise. Using this religious title, the group then published 'The Birth of a Science,' which was merely to spread the word of the wonders of Koch's nostrum. Although government and other reputable chemists and scientists branded Koch's 'glyoxylide' as a complete fraud, the group, by Hollywoodian advertising claims, amassed a fortune through its sale. Efforts to eradicate this menace were met with screams and cries of religious persecution. The true quack always assumes a religious front to protect him from a just accounting to the law. As stated by an outstanding writer on medical quacks:

"'No Quack is a perfect Quack without a pretense of religion. Deprive him of religion and you deprive him of his strongest sales talk. In that respect the Quack differs from the Bootlegger, Poacher and Abortionist. Religion is not regulated by law, until it interferes with the rights of the public. . . .'

"When the cold light of public scrutiny began to dissolve the Koch myth and after thirty years the so-called 'revolutionary science' had been shown to be what it was, a fraud and a delusion by a group of skillful propagandists, and when an aroused public began to move in on Koch, Winrod screamed that he was the victim of a diabolical plot by the Jewish race to prevent Koch and him from curing the world's ills. Winrod was labeled by the House Un-American Activities Committee: 'Gerald B. Winrod, Kansas preacher, Nazi protagonist and an unsuccessful candidate for the Senate.' Winrod was placed fourth on a list of organizations and individuals who took part in one way or another in an attempt to create a united Fascist movement.

"During all this time Schirmer's hospital was the principal focal point for the actual administering of this distilled water. Schirmer was busily engaged in piling up money at $25.00 per shot while assuring the Arkansas Eclectic Board that his motives were pure.

"The Rev. Sam Swain was a minister operating what was known locally as the National Gospel Center at Akron, Ohio. The files of the Bureau of Investigation of the American Medical Association state:

"'On the fringe of quackery in religion and an out-and-out fascist. He is not a member of the Akron Ministerial Association, but is classed by this body as an itinerant evangelistic minister with a low rating of respectability in the community.'

"That Schirmer was a devout disciple of Koch, Winrod, et al., is evidenced from his letter to a friend in New Mexico on November 4, 1950, wherein he stated:

"'I feel that each and every Doctor practicing medicine in the States owe Dr. Swain, Dr. Reilly and Dr. Winrod and the entire staff at Christian Medical Research Laboratories our most wholehearted appreciation of their efforts in manufacturing and distributing Glyoxylide and for their untiring efforts and constant fighting to promote and enlighten all of the merits of Glyoxylide.'

"This friend had written Schirmer at the suggestion of the Rev. Sam Swain who had informed him that Schirmer would advise him as to the Koch treatment. Although it is a violation of the Arkansas Statutes governing the practicing of medicine to claim to cure an incurable disease, this had very little meaning to Schirmer, who very glibly stated in his letter:

"'I can go on for hours and give you case histories of patients who have recovered, but don't forget that my percentage of symptom free patients is only 70 per cent but about 90 per cent were given up to die.'

"When the Koch Foundation faded, and when Koch decided the seashores of Brazil were necessary for his health and Rev. Swain and Rev. Winrod entered the Courts battling over the dead corpus, Schirmer, with his customary ability, transferred his affections. He is now conducting 'The Affiliate Hospital of the Lincoln Foundation.' This report will not be complete without a mention of Schirmer's recent and latest enterprise. The Lincoln Foundation is a corporation formed to market a treatment for cancer, leukemia and incurable diseases by the method of inhaling a bacteriophage. This is a patented method of treatment by one Robert E. Lincoln of Medford, Massachusetts, who claims marvelous cures for incurable diseases by inhaling some substance through the nose. This so-called cure has been condemned as being worthless by the Massachusetts Medical Society study of the Lincoln therapy. Notwithstanding the sensational claims by Dr. Lincoln and notwithstanding a statement made in a Congressional investigation to the effect that Schirmer was treating seventy-five cancer patients at his 'affiliate hospital,' Schirmer appeared before the Eclectic Medical Board of this state (according to the minutes of that board of September 20, 1952) and on inquiry from the members of the board, stated that:

"'The bacteriophage is a new medicine and at this time is used on human beings for experimental purposes only and that no claim is made by any doctor that it will cure anything.'

"This is an astounding statement in the light of the numerous patients suffering with incurable diseases which Schirmer has been handling in his Corning Hospital. The legal implications are rather severe, in that Schirmer would be legally responsible in damages for administering to human beings a supposed cancer cure which he himself reported was only in an experimental stage and was not claimed to be curative of anything. Nevertheless, the minutes of the Eclectic Medical Board reflect such a statement.

"In the spring of 1953, immediately after investigations were begun of Schirmer, he followed the pattern set by his predecessors and attempted to draw a religious veil across his operations. He deeded his hospital to certain trustees for the benefit of the Church of God of Arkansas. This deed was dated May 16, 1953, and was filed for record on May 22, 1953. Announcement was made that Schirmer had recently attended a church meeting and had been converted to this faith. An interesting feature of this conveyance is that some few days prior to the conveyance, a mortgage from the Corning Research Hospital, Inc. (which is Schirmer's corporation in which he held title to the hospital), to Schirmer's present wife, Helen J. Schirmer, in the sum of $24,488.69 was recorded at page 80 of Mortgage Book Record 30. This mortgage was dated November 1, 1951, but was not recorded until April 28, 1953, nor was it acknowledge by the Notary Public until April 28, 1953. This was just a few days before Schirmer got religion. May I call your attention to the fact that while the deed was dated November 1, 1951, and was purportedly signed by the corporation, the Corning Research Hospital, Inc. (by J. S. Schirmer, President, and Helen J. Schirmer, Secretary-Treasurer), this corporation was not incorporated until November 13, 1951, and was not in existence at the time the mortgage is purported to have been dated. It is interesting to note that there is also due and payable on these properties which Schirmer grandiloquently gave to the church, a mortgage for $18,950.00 executed December 18, 1946, on which there is a balance due to the R.F.C. and a mortgage from J. S. Schirmer to Sonja L. Schirmer (another wife) dated November 10, 1950, and filed for record February 5, 1951, securing the payment of $6,103.00 to Sonja L. Schirmer as a part of a divorce settlement. There is also on record a bill of sale from Dr. J. S. Schirmer to his son, Dr. J. F. Schirmer, conveying:

"'All surgical and hospital supplies and equipment and all office supplies and equipment located in the Corning Hospital, Corning, Arkansas, including among other things X-ray machines, and supplies, operating equipment, lights, drugs, and surgical supplies and hospital beds, and equipment.'

"In the light of the assessed valuation of this property (the general taxes for 1952 were $115.00), it is doubtful that Schirmer transferred any equity value to the church, and leads to a conclusion that Schirmer was following the steps of his idol, Koch, in seeking to give to his activities a religious flavor. Certainly such act should not retard or prevent immediate action by the responsible officials of the State of Arkansas to prohibit further activity by this individual.

"Action by the State of Arkansas against Schirmer to prohibit his unlawful activities will undoubtedly be long and expensive. There is every indication that there is money in considerable amounts behind Schirmer, that this 'golden egg' will not be lightly relinquished.

"May I respectfully suggest in conclusion that there are reputable and responsible groups in the State of Arkansas who should be more than glad to join hands in an effort to eradicate this menace to the public health. Invitation should be given them to participate in all legal proceedings. This matter is so involved and so complex that all should be invited to participate who have as their objective the promotion of the public good and the public welfare."

COUNCIL ON MEDICAL SERVICE

During the summers of 1952 and 1953 the Council's Committee on Extension of Hospitals and Other Facilities employed medical students from Northwestern University Medical School to study the physician placement programs of a number of state medical associations. Descriptions of five of these programs were published in The Journal *on Feb. 21, 1953. The following is the sixth in this series of articles.*—Ed.

PLACEMENT OF PHYSICIANS IN ILLINOIS

The state of Illinois does not at the present time have a widespread shortage of physicians. There is a slight maldistribution of physicians, as in most states, with a relatively higher percentage practicing in urban areas than rural areas. Although the Physicians Placement Service that is operated by the Illinois State Medical Society has more than 130 locations listed as open, most of which are small communities, there is not a great deal of concern about the magnitude of the number. Many of these locations represent a vacancy created by the death of a practitioner who had been practicing there for many years. In many such instances these openings do not need to be filled. The other apparent reason for the open locations is that many Illinois physicians have been called into service with the armed forces. Helping communities that have lost their physicians to the armed services is one of the main functions of the Illinois Placement Service.

One factor that serves to produce a pseudoshortage is that many of the citizens consider it a hardship to travel a distance of several miles to the office of a physician. With the fine roads in Illinois, the Illinois State Medical Society will not recognize an area as inconveniently located unless it is a minimum of 10 miles from medical care.

The southern part of Illinois has a lower ratio of physicians to population than the northern part of the state. It is financially less attractive than the northern part, and its principal industry, which is mining, is now operating at a reduced pace. Until recently there were too few hospital facilities in the southern area and in the rural areas of Illinois generally. This served as a deterrent to young physicians. However, since the advent of the Hill-Burton Program, 25 of the 42 projects approved for Illinois have been completed. At least 15 of these new hospitals are located in southern Illinois, and the availability of these new facilities has eased the situation in this area by attracting physicians. Today no person in the state is more than 30 minutes from adequate medical care and hospital facilities.

CONDITIONS PREVENTING AN ACUTE SHORTAGE

Several factors collectively prevent a serious shortage of physicians from developing in Illinois. Illinois is fortunate in having five class A medical schools, which graduated 504 physicians in 1953. Of this number, 236 are residents of Illinois, many of whom will return to their home community or establish practice in other areas of the state. The relative wealth of Illinois and the fact that every area is reasonably near a large hospital or a medical center serve to attract physicians to establish practice in the state.

To assist physicians in finding a desirable area in which to establish practice or to relocate, the Illinois State Medical Society carries on an active program in its Physicians Placement Service. This service is a function of the office of the secretary of the medical society in Monmouth, Ill.

HISTORY OF THE PHYSICIANS PLACEMENT SERVICE

The Physicians Placement Service of the Illinois State Medical Society is an outgrowth of the Procurement and Assignment Service of World War II. The secretary of the society, Harold M. Camp, M.D., served as Illinois chairman of the Procurement and Assignment Service; when the "relocation" correspondence was transferred to the files of the society at the close of the war, the information contained in these files was used by the placement service until further data could be collected by questionnaires. Since the inception of the service, Mrs. Jane Swanson has been operating it under the direction of Dr. Camp. In recent years approximately 75 physicians have been placed, principally in communities in downstate Illinois. At present the service is corresponding with 135 physicians who have requested assistance in finding a suitable location. As a result of a press release on Jan. 15, 1953, concerning the Physicians Placement Service, the number of requests, from both physicians and communities, has taken a sharp turn upward.

OPERATION OF THE PLACEMENT SERVICE

Requests from Physicians.—Physicians are referred to the Illinois office by several organizations. The American Medical Association refers all correspondence to Illinois in accordance with the policy of referring all requests for assistance from communities and physicians to all states that have an adequate placement service. But the majority of requests received by the Illinois office are received directly from physicians, by mail and by personal visits to the office in some cases.

Although all requests receive the personal attention of Dr. Camp, Mrs. Swanson attends to the details such as sending a questionnaire to obtain information on the physician's educational background, his interests, and preferences as to type of practice, and especially his draft status. Upon return of the questionnaire the physician is sent a complete list of openings, including information on each location as to facilities for home life, office space, proximity to hospital facilities, and other information contained in a 30-page mimeographed booklet. Simultaneously the physician is notified by form letter that his name has been added to the mailing list and that he will receive weekly bulletins with information on new locations as they develop. All of the physicians requesting assistance from the Physicians Placement Service are listed regardless of whether or not they are members of a county medical society.

Physicians who wish to establish a general practice are assisted directly by the Illinois office. Those who desire an industrial or institutional position or wish to practice a specialty are first sent a list of openings in Illinois and then their request is referred to the American Medical Association, which sends them a list of all such openings in the United States. The A. M. A. also refers requests for a specialty opening to the national association of that specialty if it has a placement service.

Illinois uses two methods of "follow-up" on physicians to determine whether they are still available. The most frequent is a request, included in each weekly bulletin, that the physicians notify the office if they have decided upon a permanent location or if their status has changed in any way. The second is a special form letter sent at frequent intervals asking them for similar information.

The questionnaire, which the physician completes, contains such information as his citizenship status, religious affiliation, preference as to area in the state, and the type of practice that he wants to establish. Comprehensive information is recorded concerning his present draft status and service record. Unless the physician has contacted his draft board to ascertain approximately when and if he will be called into service, he is urged to do this before arranging to set up practice. The expense of setting up practice by the young physician, coupled with the fact that it is unfair to the community to fill a location temporarily when it might be filled shortly by a physician who would be permanent, are two points used to dissuade a draft-eligible physician from setting up practice. On the other hand, if the area has a high priority rating of need, both community and physician may feel even a temporary practice worth while, in view of the possibility of one or more deferments while attempts are being made to find a replacement for him.

Requests from Communities.—The placement service is informed of communities in need of additional physicians by several means. Frequently, responsible citizens or overburdened physicians in a community will write to the Physicians Placement Service and occasionally committees representing a community will visit the office. However, all requests that have been made to the American Medical Association, the Illinois State Health Department, and Illinois Farm Publications are referred to the placement service. When informed of a community in need of a physician, the placement service sends out several questionnaires to obtain information on the location as well as to verify the need and determine the severity of the need.

The first questionnaire to the correspondent in the community must be completed and returned before the opening will be listed. Another questionnaire is sent to the secretary of the county medical society in the county in which the opening is located. In addition to this questionnaire, the placement service sends the community information on ways and means of attracting a physician. However, unless a community specifically requests a list of physicians who are available, the placement service does not send out the list of names. It would require extensive work and facilities for a community to contact the large number of physicians on the list, so the office of the placement service performs this service for the community for no charge.

The principal points of interest to a physician are extracted from all of the questionnaires and recorded. The location is immediately publicized in the weekly bulletin sent to all physicians on the mailing list. Later the opening is included in a mimeographed booklet that is sent to all physicians who subsequently are added to the mailing lists. In addition, the American Medical Association is informed so that physicians visiting its office in Chicago may obtain complete information on Illinois. To satisfy the community that the placement service is giving its request adequate attention, the community will also receive a copy of the section of the bulletin containing the release listing the community. As a "follow-up" on the opening, the placement service sends out form letters at intervals of six months inquiring of the original correspondent whether or not the opening has been filled.

Unfortunately, there are times when an opening is filled when neither the new physician nor the community informs the placement service. Many physicians using the services offered to them by the placement service establish practice in areas about which they have learned in visiting the openings listed by the placement service or return to their home towns to practice; this frequently makes medical service available to another nearby community that has been in need of a physician. Failure to notify the placement service in such instances results in additional work for all concerned.

Many communities, however, have informed the office when a physician has established practice in the community or within a convenient traveling distance. Likewise, physicians have notified the office as to the locations they have taken. These letters from the physicians and community are sent in spontaneously or as a result of the "follow-up" letters which the office sends out at frequent intervals. Another source the placement service has for determining the openings which have been filled is the lists of new members of county medical societies that are reported to the state office of the medical society.

Study of Openings.—Illinois investigates carefully each request from communities. Although a representative of the placement service is not sent to investigate the openings at the present time, information that can be used to evaluate the degree of need, as well as attractiveness to a physician, is obtained from the questionnaires that are completed by residents of the community. In these questionnaires, the number of physicians serving the area and their ages are recorded. If no physician is located there, then the distance which the people of the area must travel to reach medical care is included along with the reasons why there is no physician there now, or why the last physician left. The nearest hospitals are listed, and considerable economic information concerning the area is added. Any special arrangements that the community has made to attract a physician such as providing housing, office space and equipment, and any financial assistance that the community is offering are appended.

In the questionnaire sent to the secretary of the county medical society, questions that can best be answered by a professional person are listed. Information is obtained concerning the nearest hospital in which a new physician has reasonable assurance of staff privileges and the policy of the hospital concerning citizenship requirements for staff membership. Also included are questions relative to any special arrangements by which a new physician could augment his income.

The questionnaires contain, in addition to the above, the personal opinion of each writer as to the validity of the request for more medical personnel and the desirability of the location to a physician. These opinions, in addition to the body of information on the opening, plus any items of information contained in personal letters or within the personal knowledge of the state secretary, are all used in establishing the need and attractiveness of the opening. Dr. Camp does not believe that a visit by a representative of the state office would serve more effectively to evaluate the opening. He is of the opinion that the completeness of the information on the opening sent to available physicians allows them to judge for themselves. If sufficiently interested, they will be prompted to visit the location personally to become acquainted with all of the features that by their nature cannot be summarized in a letter.

Policy Toward Communities That Do Not Need or Cannot Support a Physician.—Communities that request aid in finding a physician are investigated thoroughly by the placement service. Unless the need is proved to be bona fide, the community is not listed as a desirable location, but, for the sake of public relations, this is being considered. There are frequent letters from persons who have office space to let or a home to sell stating there is a wonderful opportunity for a physician to establish a practice in that community and, fortunately, there is a home for sale or office space to let. These requests are investigated and passed over unless a need is established.

Dr. Camp states that frequently people are naive as to the cost of medical education and the expense of setting up a practice and expect a physician to locate in their community even though it could not possibly support him. He attempts by direct contact when possible to inform people of the expense of education and of setting up practice and of the fact that a physician is justified in expecting his practice to support him. Communities are notified when they are in an area where medical care is readily available if this fact is established by the placement service office or that the area is so sparsely settled that it could not support a physician. In the latter case, if there is need, the community is urged to undertake a program to provide emergency transportation to the nearest medical facilities such as the establishment of an ambulance service by the local undertaker or volunteer fire department.

Requests have come from small communities adjoining large towns where complete medical and diagnostic facilities are available. In such cases the local citizens desired a physician to provide a more rapid emergency service or to take night calls. When questioned, most persons would go to the nearby city "where better facilities would be available" for chronic ailments, special examinations, or even nonemergency services in preference to using a physician who might set up practice there. Dr. Camp is rather impatient with this attitude and straight-forward in explaining that they will of necessity use the nearby medical center as he will not help the town secure a "first aid man."

Recently, a small town was called to the attention of the placement service. At the turn of the century two resident physicians were located there. Within the radius of 10 miles, there were a total of 16 physicians in the horse and buggy days. Today this small town has no physician, and within the 10 mile radius there are two physicians who cover more territory and see more patients during the year than the 16 did in the old days. With the all-season roads, use of cars, and with modern facilities, there are no instances where a physician could not be available within a short time even for emergencies in Illinois.

Aiding Communities to Attract Physicians.—The Illinois Physicians Placement Service assists small communities to develop programs to attract physicians. The questionnaire to a community suggests such things as offering home facilities and office facilities. Each community is sent a reprint from the *Farm Journal* on "How to Get a Doctor," which has many suggestions, and in addition, a reprint of "If Your Town Needs a Doctor—Elletsville Shows the Way" from *Progress in Health Service*, published by the Health Information Foundation.

As reported in the Annual Reports of Officers and Committees to the House of Delegates of the Illinois State Medical Society, it is commonly the policy of the placement service to "insist that towns needing a physician have a suitable home and office space for the new doctor, before [the community is added to the list of prospective locations]. A number of them have also accumulated a sum of money placed in a local bank, from which the physician can draw at a low rate of interest, to aid in purchasing equipment, household goods, and perhaps make the first payment on the needed car. One community recently wrote stating that a home and office were available for a doctor, and there would be no rental charge the first year, and not until the practice would justify the additional expense." [1]

Effort to Publicize the Physicians Placement Service.—As a result of a state-wide press release on Jan. 15, 1953, describing the activities, accomplishments, and the services of the Physicians Placement Service of the Illinois State Medical Society, there has been an increasing number of communities requesting assistance. The fact that the services of the placement office are available for no charge to either physician or community induces many to contact the placement office. Last winter the journal of the state medical society carried an editorial concerning the placement service, and each month the office of the secretary sends out a newsletter. Beginning July 1, 1953, the newsletter will include reference to the activities of the placement service.

In the winter of 1951 the state medical society sponsored a dinner in Chicago for the interns and residents in the Chicago region. The discussion on physician placement and an invitation to all to use the service resulted in considerable response. Since this dinner was so successful, plans are being made for similar dinners in the future.

Plans for the Future.—The Illinois office has recently changed the style of the mimeographed booklet containing the list of the communities in need of a physician to the short page, single entry style used by the placement service of the American Medical Association. To further aid the communities in developing programs to attract physicians, the pamphlets prepared by the American Medical Association entitled "A Doctor for Your Community" and "Physicians Placement Service" will be widely distributed. Reprints of "Country Doctor—Does Your Community Need One?" from *Farm and Ranch* will be distributed also. To further aid the inquiring physicians, additional information and printed material will soon be sent to them. Information on the per capita wealth of each county in the state will be supplied by the Illinois Public Aid Commission. Complete data on each approved hospital in the state is being compiled and will be furnished in addition to reprints of "Rural Practice Can Be Fun" from the *Journal of the Student American Medical Association.* At the present time, work is underway on the preparation of a brochure containing a scenic and historic map, a road map of Illinois, letters of invitation, and complete descriptions of all counties and locations needing a physician.

Since the relatively small amount of publicity of the placement service of Illinois has yielded so many requests, it is planned to further publicize the services that the Illinois State Medical Society offers to communities and physicians. The state of Illinois is indeed fortunate in having such a progressive, well organized Physicians Placement Service.

ACTIVITIES RELATED TO THE PLACEMENT PROBLEM

There are many factors contributing to the shortage of physicians in rural areas. The maldistribution of physicians between the rural and urban areas is the predominant cause. Encouraging physicians to establish practice in rural areas is one means of alleviating the shortage. Another means is to increase the supply of general practitioners so that the rural areas will get more physicians. By providing a placement service designed to aid especially the rural areas, the Illinois State Medical Society is partially alleviating the shortage. This direct effort on the part of the medical profession is supplemented by other activities designed to interest physicians in general practice and in locating in small communities.

Loan Funds.—The Illinois State Medical Society and the Illinois Agricultural Association have a joint fund that now grants $1,250 annually for four years of their training prior to internship to each of 10 students. These students are selected from the 10 Illinois counties most in need of physicians. The loan is made for four years at 2% interest per annum and the student may attend any class A medical school. In return, the student agrees to return to a community in an approved county of less than 5,000 to practice for a minimum of five years. During these five years of practice the young physician has opportunity to repay the loan according to the original contract. There are at present 42 students in various phases of their medical education or military career under this program.

Curriculum Programs.—The University of Illinois College of Medicine has an internship designed to prepare physicians for general practice. Although the internship is open to all students, it is especially designed for students who expect to practice in rural areas.

Plans are being studied for selective admission to the school to encourage the location of graduates in small towns and rural areas. Also being studied is a program for the establishment of extramural faculty positions and supervised residencies in rural hospitals.

Stritch School of Medicine of Loyola University has placed particular emphasis on general practice in the training of its students. The school catalogs material on rural opportunities and supplies information and advice on these openings to returning students, interns, and others. This service is to be extended and further publicized through the school's alumni newspaper.

Postgraduate and Refresher Courses.—The University of Illinois College of Medicine offers a program of postgraduate studies for general practitioners in rural and urban areas.

---

1. Annual Reports of Officers and Committees, 1953 Annual Meeting, Chicago, Illinois State Medical Society, 1953, p. 22.

The Committee on Postgraduate Education of the Illinois State Medical Society presented nine major and three minor conferences throughout the state in 1952. At each program the staff from a prominent hospital or one of the five class A medical schools in the state presented a program on selected medical topics. All the physicians in a wide radius were invited to attend, and each program was well received by those attending. This committee has recently undertaken to raise funds for a detailed survey of postgraduate education in Illinois.

Clinics.—The University of Illinois Division of Services for Crippled Children holds general clinics for handicapped children at various locations throughout the state each month.

Associated Programs.—The Illinois State Medical Society and the Illinois Agricultural Association cooperate in attempting to increase medical service throughout the state. In 1951, for instance, they persuaded the University of Illinois College of Medicine to admit 15 more students to the freshman class.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Blood Transfusion: Death from Hepatitis Following Use of Pooled Blood Plasma.—This was an action for damages seeking to impose liability on the State of New York for the death of the decedent as a result of virus infection caused by transfusion of pooled blood plasma distributed to the hospital by the state at the request of the Red Cross. The court of claims entered a judgment dismissing the claim (Parker v. State, 105 N.Y.S. (2) 735; *J. A. M. A.* **148**:1359 [April 12, 1952]), and from this judgment the plaintiff appealed to the supreme court, appellate division.

After the close of the last war, quantities of dried blood plasma, which had been collected from donors by the American Red Cross for the armed services, were declared surplus property by the government and turned back to the Red Cross to distribute for charitable purposes under the authority of a federal statute. The Red Cross requested the various states to undertake the free distribution of the plasma to hospitals for public use and the health department of the State of New York undertook the task of distributing within the state. Through the local agency of the Red Cross in Westchester County, some of it was sent by the state in 1947 and 1948 to the Northern Westchester Hospital at Mt. Kisco.

It was known to the medical profession, from the experience that had been gained with whole blood transfusions and with transfusions derived from dried blood plasma, that there was some risk of transmitting virus diseases, especially a form of serum jaundice; and that this risk was greater in the case of pooled dried plasma because the virus of one infected donor would contaminate the rest of the plasma with which it was in contact in the same container. Nevertheless there were circumstances when sound medical judgment indicated the use of pooled dried plasma. There are varied expressions in the record before us, said the court, as to the risk involved in the use of this type of plasma and the limitations of its use. A good statement is contained in the report of the Committee on Blood and Blood Derivatives of the American Red Cross, copies of which were sent to all state health officers in August, 1947. The report was published in the *Journal of the American Medical Association,* November 15, of that year. The conclusion of this statement, on which the plaintiff places heavy emphasis here, is that all practicing physicians "should be reminded" of the "potential risk" in the administration of pooled plasma and should be "urged to restrict its use" to "chiefly serious emergencies, when its use is clearly indicated and when safer agents such as whole blood or serum albumin are not available."

On the morning of Nov. 21, 1948, the claimant's husband was found unconscious along a road. He was picked up by a passerby and taken to the Northern Westchester Hospital. He had a cerebral concussion and was in shock and critical condition. A physician, who undertook his treatment at the hospital, prescribed a transfusion of blood plasma. Plasma that the Red Cross had received from the government and that the New York Health Department had distributed for the Red Cross was used for this purpose. The plaintiff recovered from the acute effects of the concussion and was discharged from the hospital as improved after eight days. A little over two months later, he became ill from a form of serum jaundice and died on Feb. 12, 1949.

The Court of Claims found the jaundice infection and death the result of transmission of the virus by the transfusion derived from the pooled plasma, but it granted judgment dismissing the claim on the ground that the state thereby incurred no tort liability. The state in undertaking to distribute the plasma to hospitals for the Red Cross, said the appellate division, had a right to expect two things, (*a*) that the hospitals would be guided by the judgment of the medical profession in the circumstances indicating the use of the plasma and (*b*) that the profession would use an accepted standard of professional judgment in prescribing its use. If a physician prescribed the serum mistakenly or by an erroneous professional judgment, the legal responsibility for such an error could not be brought home to the state under any admissible theory of tort liability merely because it had acted for the American Red Cross as an agent of distribution. The record demonstrates that there are circumstances in which careful medical judgment would regard the immediate institution of shock treatment as outweighing greatly the mathematical possibility of virus infection. There is proof that there were other and possibly "safer" types of transfusion material in the hospital, but the record would sustain a finding that the plasma could more quickly be brought into use, when the hour of admission of the patient to the hospital and the need for preliminary blood tests, requiring the availability of both time and technicians, are kept in mind.

We must assume from the record, the court continued, that the physician's course of treatment was based on sound medical judgment. Certainly the state would incur no tort liability if the physician who treated the patient had acted with that kind of medical judgment. Even if he had acted mistakenly or had made a wrong decision, the state would not be responsible unless in the exercise of reasonable care it could be required to foresee such a result. The state was bound to know that the use of this type of plasma involved some risk, but with that knowledge it also knew that its use was justifiable when the risk involved ought, in good medical judgment, to be taken. It had a right to expect that the profession would use an agency of limited medical usefulness under limited conditions. The level of expectation of danger imposed on the State did not rise above that which would be required of a reasonably well-informed medical officer in carrying out the distribution program of the Red Cross, and the state could rest safely in the expectation that the plasma would be used in a recognized hospital only under competent professional prescription. We are of opinion that the state's liability has not been demonstrated.

Accordingly the judgment of the Court of Claims in favor of the State of New York was affirmed. *Parker v. State, 112 N. Y. S. (2d) 695 (New York 1952).*

Berylliosis.—The largest number of cases of acute beryllium intoxication have occurred in plants engaged in the extraction and processing of beryllium, and the largest number of cases of chronic berylliosis have been reported in connection with the manufacture of fluorescent lamps. Since 1940 DeNardi and associates have treated 468 patients with various types of beryllium intoxication observed among workers in three plants with a total employment of 3,027 persons and a present active personnel of 369. Among the 431 patients with acute beryllium intoxication, there were 10 fatalities in the pneumonitis group. The incidence of cutaneous berylliosis among workers in the beryllium industry has been reduced in recent years by preventive measures from 25 to 2% and the respiratory syndromes almost to zero. The eczematous type of dermatitis is caused by allergic sensitivity to beryllium compounds. Beryllium patch tests on patients with berylliosis, on controls, and in similar pathological conditions suggest that beryllium dermatitis is due to hypersensitization and that the patch test is an important tool in differential diagnosis. Clinical and laboratory data were obtained on 75 patients who recovered from tracheobronchitis and pneumonitis. Eight deaths occurred among the 37 patients who had chronic types of beryllium intoxication. The presence of beryllium in tissues and in urine is indicative of exposure to beryllium. The amount detected by present analytic methods does not bear any relationship to the diagnosis of berylliosis per se or to the severity of the disease if present. Beryllium remains in tissues and is excreted for years after the patient has been removed from exposure and is without evidence of beryllium poisoning. No persons included in the survey of patients recovering from acute pneumonitis developed the chronic or delayed form of berylliosis. Of the eight instances of chronic berylliosis of occupational origin, one patient had a medically established diagnosis of acute tracheobronchitis, while four others gave histories suggestive of acute tracheobronchitis during brief occupational exposures to beryllium. Treatment of berylliosis is mainly symptomatic, but recent observations suggest benefit from the use of corticotropin and cortisone in both the chronic and the acute manifestations.

Central Neurological Complications of Hypoparathyroidism. O. Sugar. —p. 86.

Progressive Neuropathic (Peroneal) Muscular Atrophy.—Brodal and associates point out that most neurologists believe that one is justified in considering as a disease entity the condition variously called "peroneal muscular atrophy of the Charcot-Marie-Tooth type," "progressive neuritic muscular atrophy," or "spinal neuritic form of progressive muscular atrophy." The available evidence concerning its etiology is in favor of a disorder of the spinal cord and of peripheral nerves being the primary process, the muscular changes being secondary. The authors report histological observations on 20 muscle biopsy specimens from 14 patients with progressive neuropathic muscular atrophy of the Charcot-Marie-Tooth type. Eight of the patients were reexamined clinically after periods of up to 11 years. The mode of inheritance appears to be dominant. In early stages atrophy of muscle fibers in groups was typical. There was some increase in the hypolemmal nuclei and in connective tissue, but less in adipose tissue. Some fibers were hypertrophic. In disease of more than four years' duration atrophy of fibers in groups was still present, but less prominent. There was greater increase in connective tissue and a definite increase in hypolemmal nuclei. Degenerative changes in the nuclei (pyknotic nuclei, nuclei with a halo, "sick" nuclei) became conspicuous, as well as degeneration of sarcoplasm (granulation, vacuolation, cloudy swelling) and disintegration of myofibrils. Structurally preserved but extremely atrophic muscle fibers may, however, be seen even in cases of long-standing disease. The histological findings are compared with those in amyotrophic lateral sclerosis and other progressive muscular atrophies due to disease of peripheral motor neurons and with those occurring in peripheral nerve injuries in man and animals. It is concluded that the muscular changes in the disease under consideration are due to a disorder of peripheral motor neurons. The affected muscle fibers may either atrophy slowly and reach a very advanced degree of atrophy with preservation of their cross striations, or they may undergo degeneration at a relatively early stage. The occurrence of degenerative changes does not necessitate the assumption of factors other than denervation as responsible for the muscular changes. The more frequent occurrence of degenerative changes

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

in the muscle fibers and their nuclei in Charcot-Marie-Tooth atrophy than in other muscular atrophies due to disease of peripheral motor neurons may be explained by the longer duration of the disease, time being available for the late stages of the process to develop. Muscle biopsies on patients suspected of having the Charcot-Marie-Tooth type of atrophy may be of diagnostic value.

Neural Toxicity in Tuberculous Patients Treated with Isoniazid.—Gammon and associates describe a new syndrome of neural toxicity that they observed in tuberculous patients treated with isoniazid. The fully developed syndrome apparently has not previously been described, and no suggestion of it appeared in the animal studies. The patients all had advanced pulmonary tuberculosis and had received a large quantity of the drug. The authors examined 14 patients from a larger group of 46 with similar complaints observed in a series of 408 patients receiving the drug. Tingling or painful paresthesias of the feet and legs were followed by weakness or paralysis, with loss of deep reflexes first at the ankles and then the knees. The hands were affected in a few instances. The process was subacute and subsided promptly on withdrawal of the drug, unless it had progressed to a severe stage; in that case several weeks were required for even partial recovery. The dose which induced these signs varied from 4.5 to 13.5 mg. per kilogram of body weight and was in the range in which toxicity is to be expected. The neuropathy puts a limitation on therapy with higher doses. Since this paper was presented, peripheral neuropathy has been mentioned as a toxic side-effect of therapy with hydrazide derivatives of isonicotinic acid in another report, but no details of the cases were reported.

Clinical Analysis of Subtotal Gastric Resections.—Subtotal gastric resection as practiced today conforms to one of two general types, depending upon whether the duodenum or the jejunum is utilized for the reestablishment of gastrointestinal continuity. If the duodenum is utilized, the operation is known as a Billroth 1; if the jejunum is employed, the procedure is a Billroth 2, or one of its modifications. The material for this study includes all gastric resections, except total gastrectomies, performed in a Seattle hospital from Jan. 1, 1948, through March 31, 1952. The decision whether the reestablishment of continuity would be according to the Billroth 1 or the Billroth 2 technique depended on the preference of the surgeon. Many of the Billroth 2 operations might have been done as Billroth 1 procedures, if the operating surgeons had so preferred. The Billroth 1 resection was performed in 104 patients and the Billroth 2 resection in 135 patients. These two series were compared from the standpoint of age, sex, duration of history, indications for surgery, pathology, postoperative complications, and follow-up evaluation. A comparison was made also with similar studies made elsewhere. Data on extent of resection indicate that it is possible to do an adequate resection by the Billroth 1 method. The incidence of dumping for the two series is essentially the same. In 6.5% of the Billroth 1 procedures the results were considered poor, in contrast to 25% of the Billroth 2 procedures. The over-all mortality rate for the Billroth 1 series was 3.8%; 7.4% for the Billroth 2 group. In cases of peptic ulcer the mortality rates are 2.2 and 8.2% respectively. Postoperative body weight was better maintained in the Billroth 1 than in the Billroth 2 group. There were no recurrent ulcerations in the Billroth 1 series. There were three known and two possible recurrent ulcerations in the Billroth 2 series. The Billroth 1 operation can and should be employed oftener. At the authors' hospital, the Billroth 1 resection is now performed more frequently than the Billroth 2.

Bleeding Peptic Ulcer.—Saltzstein and associates analyze 402 cases of massive upper gastrointestinal hemorrhages observed at Harper Hospital in Detroit over a period of five years. There were 343 cases of peptic ulcer (278 duodenal, 53 gastric, and 12 marginal) and 59 cases of upper gastrointestinal bleeding. Ten per cent of the hemorrhages from peptic ulcer were severe; shock was prevented only by the administration of 500 cc. of blood every eight hours. Of the 343 patients 275 were treated medically and 68 were treated surgically. Four-fifths of those treated surgically bled mildly, but many had bled previously. Four deaths (5.9%) occurred in the surgically treated patients and 14 (5.1%) in the medically treated. Several of the deaths in the medically treated patients occurred in those with associated cardiovascular conditions. The anoxia of gastrointestinal hemorrhage may have precipitated cardiovascular accidents. Three of the 14 patients who died while under medical management died in shock of uncontrolled hemorrhage. Half of the 343 patients with bleeding peptic ulcer had hematemesis, and half had melena, but of the 18 who died 14 had hematemesis and 4 had melena. Pyloric obstruction did not increase the seriousness of the bleeding. Five of the 343 patients had associated perforation. The fatalities from bleeding gastric ulcer were three times as high as those from bleeding duodenal ulcers. About half of the fatalities occurred during the first episode of bleeding. The treatment of massive upper gastrointestinal hemorrhage consists of giving sufficient blood to prevent the ill effects of anoxia on the liver, the myocardium, and the brain. The decision to operate does not necessarily have to be made in 48 or 72 hours if the patient can be maintained without anoxia. Patients with repeated bleeding, in whom the blood pressure drops while they are under observation, should be operated on before leaving the hospital, because of the likelihood of sudden fatal hemorrhage occurring months afterward. Of the patients with acute hemorrhage from peptic ulcer, 10 to 15% have no ascertainable history of ulcer; this is especially true of older patients. Uncontrollable hemorrhage following resection frequently comes from the duodenal stump, may come from the anastomotic suture line, and sometimes may be relieved by manually evacuating large clots from the residual gastric stump. This may allow the stomach to contract sufficiently to arrest the bleeding.

Familial Pheochromocytoma.—This report is concerned with the diagnosis and successful removal of bilateral pheochromocytomas in two sisters and a brother. The first patient, an 18-year-old girl, was admitted to the Mayo Clinic with the chief complaint of blurring of vision. The family physician had found albumin in the urine and a blood pressure of 200/160 mm. Hg. Rest in bed, sedation, and low-salt diet were without benefit. Approximately one week before admission to the clinic, the patient had noted dull frontal headache and occasional dull pain in the right costovertebral angle. The tentative diagnosis was malignant hypertension. Careful questioning revealed that for several months the patient had been aware of tachycardia and that for the past five years she had experienced episodes of palpitation followed by generalized weakness of two to three days' duration. Four months before admission her blood pressure had been recorded as normal.

In view of the positive results of tests for pheochromocytoma, the relatively short clinical history of severe hypertension in a young woman, and the marked fluctuations in blood pressure, exploratory operation was deemed advisable. A multilobulated tumor was found on each adrenal and was removed. One year after operation her blood pressure was 110/68 mm. Hg. She appeared to be in excellent health and had had no recurrence of symptoms. A histamine test for pheochromocytoma at this time gave negative results. The patient stated that her sister had high blood pressure. Familial occurrence of pheochromocytoma was suspected. This suspicion proved to be true; bilateral pheochromocytomas were subsequently removed from the 28-year-old sister and from the 25-year-old brother. It was also ascertained that the father of these three patients had died at the age of 42 from a cerebrovascular accident with a history of attacks suggestive of pheochromocytoma. This is probably the first report of the diagnosis and successful removal of bilateral pheochromocytomas from three members of the same family and of the removal of bilateral pheochromocytomas at a single operation. The authors state that Calkins and Howard diagnosed bilateral pheochromocytomas in 1947, and pointed out the familial incidence, one of their patients being the niece of the other.

Occlusive Auricular Thrombi. J. B. Wallach, L. Lukash and A. A. Angrist.—p. 77.

Diagnosis of Mitral Regurgitation.—Abelmann and associates point out that criteria for the diagnosis of mitral regurgitation are undergoing a reexamination, because, while mild regurgitation may not affect either the operative risk or the prognosis of mitral valvuloplasty and may even be partially corrected by valvuloplasty, marked regurgitation affects the prognosis unfavorably and is a contraindication to the conventional finger fracture valvuloplasty or commissurotomy. They review the clinical diagnostic findings in a group of 63 patients with rheumatic mitral stenosis who underwent mitral valvuloplasty. Fatigability, apical systolic murmur, heart chamber enlargement, systolic expansion of the left auricle on fluoroscopy, auricular border electrokymogram and esophagogram, as well as the relationship of the timing of heart sounds in respect to cycle length as shown by the phonocardiogram, were evaluated as criteria of mitral regurgitation in patients with rheumatic mitral disease. Mitral stenosis was found to be accompanied by insufficiency oftener than is generally held and clinically suspected. Marked mitral regurgitation may exist with but a faint apical systolic murmur, and, conversely, tight mitral stenosis may be accompanied by a loud apical systolic murmur. In general, however, a systolic murmur of grade 3 or louder at the apex indicates moderate to marked mitral regurgitation. By itself, a loud apical systolic murmur does not contraindicate valvuloplasty for stenosis. Severe fatigability and weakness overshadowing dyspnea is often associated with marked mitral regurgitation but may be found in patients with predominantly mitral stenosis and may be absent in marked mitral regurgitation. Left ventricular enlargement in the absence of aortic valvular disease, hypertension, or myocardial failure speaks for mitral regurgitation, although marked stenosis may occasionally coexist. Aneurysmal dilatation of the left auricle indicates marked mitral regurgitation. Systolic expansion when seen in the posteroanterior projection is presumptive evidence of marked mitral regurgitation. In the oblique position this sign may be present in tight mitral stenosis and it may be absent in marked mitral regurgitation. The auricular esophagogram did not improve clinical estimation of mitral regurgitation. Phonocardiographic records did not appear sufficiently consistent to be of diagnostic value in mitral regurgitation. The authors discuss the possible hemodynamic and technical causes of the difficulties encountered in correlating systolic expansion of the left auricle as assessed by fluoroscopy, esophagograms, and electrokymograms with the degree of mitral regurgitation. They reassert the feasibility of correct preoperative diagnosis of marked mitral regurgitation in most cases of mitral valvular disease under consideration for valvuloplasty, but no single criterion may be relied upon; consideration of all clinical findings usually allows correct assessment.

Pathogenesis of Herpes Zoster.—The patient reported by Cheatham was a woman, aged 50, who had been given several courses of roentgen irradiation for Hodgkin's disease confirmed by biopsy of an axillary lymph node. Later, when periumbilical pain developed, she was treated with nitrogen mustard. A vesicular rash appeared accompanied by high fever. She died on the 18th day after the onset of pain. Microscopic examination of the vesicals revealed classical lesions of herpes zoster. Intranuclear inclusion bodies were demonstrated within the esophageal mucosa, myenteric plexus of the stomach, dorsal root ganglia, and a sympathetic ganglion at the level of the affected dorsal root ganglia. Similar inclusions were seen within cells in lesions of the pancreas, adrenals, and one ovary, associated with focal necrosis. Such lesions have not been previously described in zoster. It is postulated that the virus entered the body via the sympathetic nerves of the esophagus and migrated by the sympathetic nerves to the dorsal root ganglia, eventually reaching the skin by centrifugal spread along the respective peripheral nerves. The disseminated visceral and cutaneous lesions resemble those described in varicella. The viruses of herpes zoster and varicella are probably identical. In varicella the lesions probably result from a hematogenous spread in a nonimmune individual, while in typical zoster they are tentatively considered to result from neurogenous spread in a person with humoral immunity. The respiratory and gastrointestinal tracts probably serve as portals of entry in most cases of herpes zoster. An incidental finding in this case was the apparently inconsequential growth of Histoplasma capsulatum in one adrenal gland.

Treatment of Early Syphilis.—In May, 1948, a study was initiated on the efficacy of a single treatment with procaine penicillin in oil containing 2% aluminum monostearate (also known as PAM) in early syphilis at Bellevue Hospital. To date, 174 patients have been treated and have been followed clinically and serologically for 9 to 60 months following completion of therapy. The purpose of this study was to determine what could be accomplished with a single injection, since such schedules of therapy are of special value in those underprivileged countries where the majority of patients must be treated in the shortest period of time and on an ambulatory basis in rural clinics. Originally, the authors administered a single injection of 1,200,000 or 2,400,000 units of the penicillin preparation, but since June, 1950, they have been treating alternate cases of early syphilis with a single treatment of 2,400,000 or 4,800,000 units. It was found that a single injection of 1,200,000 units of procaine penicillin in oil with 2% aluminum monostearate is a satisfactory procedure for seronegative and seropositive primary syphilis. If a single treatment for secondary syphilis is used, it seems advisable to give 2,400,000 units of procaine penicillin in oil with 2% aluminum monostearate.

Surgical Treatment of Gastric Malignancy.—Three basic surgical methods are utilized in the treatment of gastric malignancy: distal subtotal gastrectomy, proximal subtotal gastrectomy, and total gastrectomy. Kirschner and Garlock report results with distal subtotal and total gastrectomy. Among 283 patients operated on for gastric malignancy during the 15 year period from 1937 to 1951, 161 were subjected to the subtotal and 24 to total gastrectomy. Resection was possible in about two-thirds of their patients. Gastroenterostomy was performed in eight patients, local excision in two, and laparotomy in 88. There were 12 surgical deaths among the 88 patients undergoing subtotal gastrectomy more than five years ago. Of the 76 who survived the operation, 18 were alive at the time of this report. Of the 24 patients who underwent total gastrectomy between 1940 and 1951, four died during the operation. Although the percentage of patients with lymph node involvement was about the same in the two groups (undergoing subtotal or total gastrectomy), the authors emphasize that there is not a single long-term survivor among those subjected to total gastrectomy. One patient lived for three years and died of the gastric cancer. There is considerable speculation concerning the advisability of increasing the scope of gastric resection to the point of total removal. The biological behavior of the growth itself and the response of the host to its activity may be more important in the long-term survival. Reports indicate that the large number of total gastrectomies has been followed by increasing morbidity in term of impairment of digestive function, anemia, malnutrition, stricture at the anastomosis, diarrhea, and loss of earning power. The vast majority of these survivors become emaciated digestive cripples. The concept of variable biological behavior in cancer is finding wider acceptance, and while it should not lead to fatalistic attitude in the approach to the management, the authors feel that subtotal gastrectomy is the procedure of choice for malignant lesions in the distal portion of the stomach.

Importance of Age of Patient for Prognosis of Carcinoma of Thyroid.—In the classification which Crile and Hazard employ, cancers of the thyroid are divided into the papillary and nonpapillary tumors, each of which has a characteristic natural history and clinical behavior. In some tumors, which behave clinically like papillary carcinoma, sparsity of papillary areas may make it difficult to classify thyroid cancer on the basis of morphology alone. Even if alveolar areas predominate in papillary carcinomas, these tumors will follow the behavior pattern of the papillary type of carcinoma and the patient's prognosis will be good. The nonpapillary type of thyroid cancer follows the age distribution of cancers elsewhere, occurs in older age groups, and usually is a highly malignant tumor. If areas of anaplasia are present, the tumor behaves like a highly malignant nonpapillary cancer, even if papillary areas are present. Since alveolar variants of papillary carcinomas may resemble nonpapillary adenocarcinoma of much higher malignancy, the classification of carcinoma of the thyroid should take account of the clinical as well as the morphological features. One of the most important and most neglected prognostic features of a cancer of the thyroid is the age at which it occurs. In 15 carcinomas of the thyroid that the authors observed in patients under 40 years of age, all were classified as papillary types of carcinoma and none developed recurrence or metastasis from 3 to 15 years after operation. In a larger series of 105 patients with thyroid carcinoma, all seen in the past five years, there were 43 patients under 40 years of age. Forty-one of these 43 patients had carcinomas of the papillary type and two had angioinvasive adenomas, which are considered to be of low malignancy. The vast majority of the cancers of the thyroid occurring in patients under 40 years of age behave like papillary carcinomas, regardless of whether alveolar or papillary elements predominate. The rare nonpapillary type of cancer that occurs in persons under the age of 40 is usually an angioinvasive adenoma with a low degree of malignancy. The prognosis in this age group is almost uniformly good if an adequate operation is performed. The surgeon need not be too alarmed if the tumor of a young patient is predominantly adenocarcinoma or alveolar carcinoma; he can assume that the outlook is as good as if the morphological arrangement were predominantly papillary.

Stability of Penicillin Products for Aqueous Injection.—Procaine penicillin G and buffered crystalline penicillin G (sodium or potassium) for aqueous injection is marketed as a dry powder that is reconstituted with a suitable diluent just prior to use. The usual concentration for this product is 300,000 units of procaine penicillin G and 100,000 units of buffered crystalline penicillin G (sodium or potassium) per milliliter. Buckwalter and Duda report observations on its stability at normal and accelerated temperatures for long periods of time. Random samples of finished 5 or 10 dose vials were taken from each production batch and stored under various temperature conditions. Accumulated data indicate the excellent stability of procaine penicillin G and buffered crystalline penicillin G for aqueous injection at 52 to 56 C (125.6 to 132.8 F) for 12 to 18 months and at 22 to 28 C (71.6 to 82.4 F) for two to four years. After two to four years at 22 to 28 C, the maximum loss was 7.2%. In the reconstituted state, this product is stable for one to two weeks at 5 to 10 C. Losses of less than 10% in penicillin activity are regarded as insignificant and of little consequence in judging the usability of a penicillin product. It appears that this product can be stored for several years, even in tropical countries, without any serious decomposition of the penicillin.

Long Survival with Hemiplegia Incident to Paranatal Anoxia: Case of Cerebral Spastic State with Death from Cardiac Failure at 80 Years of Age. C. B. Courville.—p. 110.

Cerebral Anoxia and the Causation of Epilepsy.—Courville and Nielsen enumerate many close associations between cerebral anoxia and the occurrence of convulsive seizures. They point out a number of facets of the problem that suggest that many of the group of so-called idiopathic or essential epileptics have, during the birth process, been subjected to minor injuries, and perhaps overlooked episodes of neonatal anoxia. Convulsive seizures are shown to be one of the most characteristic of all postanoxic symptoms as shown in both experimental and human instances of this condition. Cerebral anoxia is accompanied by dysrhythmias that are indistinguishable from those of the so-called idiopathic form of seizure. The actual cellular mechanism is suggested by the action of a peculiar form of anoxia produced by cyanides, a metabolic poison which apparently produces some change in the protoplasm of the cell and makes it impossible for it to use oxygen. Convulsive seizures, as one of the postanoxial manifestations, occur as the result of some interference with oxygenation within the nerve cells. A disturbance of internal respiration may be the ultimate exciting factor in the production of a seizure, although the causes of this disruption may be many.

Hyperkinetic motor phenomena, including grand mal seizures, have been provoked by experimental neonatal anoxia. The frequent association of convulsions with other manifestations of asphyxia at birth also points in the same direction. This conclusion is further supported by the observation that the histological characteristics of epileptogenic lesions removed at operation present signs of anoxemic etiology. The final argument, on a statistical basis, is that first-born children, also most likely to suffer from the effects of neonatal anoxia, are apparently more apt to develop convulsive seizures than are subsequent siblings.

Breast Cancer After Hormone Therapy.—The 18 patients presented in this report were selected from a total of 27 on whom mastectomies had been performed after hormone therapy. Nine were eliminated because they had received roentgen ray therapy or came from other hospitals with insufficient clinical information. Four of the 18 were considered operable when first examined. They were given diethylstilbestrol (Stilbestrol) for periods of 5, 10, 20, and 25 days prior to operation in an attempt to observe early regressive changes. The tumors of the remaining 14 patients were incurable by operation at the onset of therapy. On steroid-hormone treatment in these cases, there was demonstrated regression by healing and epithelization of ulcers; softening, mobilization, and disappearance of deep-seated masses; shrinkage of protuberant tumors; and the disappearance or reduction in size of skin nodules and enlarged lymph nodes. The pathological aspects of the phases of regression were investigated. Regression was preceded by simultaneous loosening of the stroma and necrobiosis of the malignant cells. Subsequently collagen reformed in the regressing areas and produced tumor-free scars of increased density. These alterations resulted in the clinical impression of softening, shrinkage, and mobilization of the tumor. Regression ranged from partial alterations in limited areas to almost complete fibrosis of a primary tumor and its lymph node metastases. Similar changes were observed in tumors of untreated patients in the same age group, but the degree of change was nowhere near that observed in the hormone-treated tumors. It appears that a preexistent reactive response to tumor had been further stimulated by the hormones. There is also visual proof that some malignant cells, presumably the source of later reactivations, survive even in extensively regressed tumors, and that this survival is dependent in some degree on the location of the cells within ducts with hyperplastic elastica, lymphatics, and densely sclerotic areas. The clinical impression that slowly progressing tumors respond best to treatment is confirmed in the finding that medium and low grade carcinomas tend to show better responses. Among the primary carcinomas, those characterized by abundant sclerosis and periductal elastic tissue hyperplasia are particularly susceptible to hormone-induced regression. Similarly constituted tumors failed to regress equally, indicating that the morphology of the stroma of the tumor was not the sole determinant in its response to the hormones. It appears that these regressions were in part the result of an unusual hormonal stimulation of a natural process of repair.

Five Year Survival Rate for Gastric Cancer.—Raffl and Kelley base their report on patients admitted to two of the hospitals of the Syracuse Medical Center during the years 1937 to 1951 with the diagnosis of cancer of the stomach. The mean age of these patients was 63.1 years. The disease predominated in the older age groups and in men; the male to female sex ratio was 2:1. Weight loss, pain, vomiting, anorexia, and weakness were the five commonest symptoms with an average duration of 8.5 months before hospitalization. Gastric analysis showed achlorhydria in 70% of the cases; 29% showed hypochlorhydria and only 1%, hyperchlorhydria. Roentgen examination proved helpful in diagnosis, providing a correct diagnosis of gastric cancer in 77% and indicating other gastric abnormalities in 17%, a total of 94%. The operability rate of those admitted with a diagnosis of carcinoma of the stomach was 76%. Of the patients operated on, 47% were given a curative resection (36% of the total) with a mortality of 14%. Palliative surgery provided little relief and was accompanied by a high mortality. Of those undergoing resection only three lived five years without recurrence of their carcinoma; this gives a five year survival rate of 6.6%. The over-all five year survival rate was 2% for all patients admitted to the hospital with a diagnosis of carcinoma of the stomach. The authors feel that in their hands, at least, the results of subtotal resections for carcinoma of the stomach have been very discouraging.

Cardiac Resuscitation from Ventricular Fibrillation.—Ventricular fibrillation may be caused by coronary occlusion, electrocution, digitalis and digitalis-like drugs, chloroform, chloroform and epinephrine and other compounds of epinephrine, mechanical, chemical and thermal trauma, and interventions, particularly those involving the thorax and the heart. It may occur as an agonal event. In some species of mammals, such as the cat, ventricular fibrillation may stop spontaneously; in dogs and in human beings fibrillation is not spontaneously reversible. It can be stopped by various procedures and drugs. The efficacy of electrical countershock, cardiac massage, epinephrine, and procaine in stopping electrically induced ventricular fibrillation and restoring a competent ventricular contraction was studied in 75 anesthetized dogs. It was found that countershock is a reliable means of stopping fibrillation. However, it must be preceded by cardiac massage if not applied promptly after initiation of fibrillation. Epinephrine helps restore a competent ventricular contraction once fibrillation has been stopped by countershock, but it increases the incidence of recurrence of fibrillation. The doses of procaine that constitute a reliable means of stopping fibrillation depress the rhythmicity of the heart to such an extent that the cessation of fibrillation is followed by prolonged periods of cardiac standstill.

Patent Ductus Arteriosus with Pulmonary Hypertension.—Hultgren and associates report on eight cases of patent ductus arteriosus associated with pulmonary hypertension. Catheterization was done in six of these and autopsy in three. Four of the patients had evidence of right to left or reversed shunt through the ductus, and three of these presented the clinical picture of chronic cyanotic congenital heart disease. Four patients had no evidence of a right to left shunt, but presented an atypical clinical picture with absence of the characteristic continuous murmur and evidence of enlargement of the right ventricle. Two of these patients improved greatly following ligation of the ductus. This study suggests that the basis of this syndrome is an elevation of the anatomic resistance of the pulmonary vascular bed with a resultant increase in pulmonary artery pressure. The cause of this increased resistance is not apparent, but thrombosis with recanalization, and in one instance a diffuse arteritis, have been demonstrated. Clinical evidence suggests that in some cases the disease has been present since birth. Surgery seems indicated in those cases in which a right to left shunt is not present, but ligation may be dangerous or fatal in instances where a right to left or "reversed" shunt is present. The most important single diagnostic study that will detect the presence of a ductus with a reversed shunt consists of the determination of the oxygen content of simultaneously drawn blood samples from the right brachial and femoral artery at rest and during exercise. Cardiac catheterization is necessary to detect accurately the "atypical" ductus without a right to left shunt, which may be erroneously diagnosed clinically as an atrial septal defect with pulmonary hypertension or "primary" pulmonary hypertension.

Discography in Diagnosis of Herniation of Intervertebral Disks.—Davies and Peirce show that an absorbable contrast medium may be injected to outline the nucleus pulposus following insertion of a fine lumbar puncture needle through the posterior annulus fibrosus in any of the three lower lumbar spaces. This procedure is called discography. It makes possible the demonstration of various pathological conditions of the intervertebral disks, especially herniation. The technique is described, and the results of 28 discogram attempts in 23 patients are recorded. In five patients the results were unsatisfactory in one or two interspaces. In all of these a repeat examination was satisfactory. A total of 30 ruptured disks were found in 20 patients; two patients showed no evidence of disk rupture. Of the 20 patients with ruptured disks, 12 were treated by exploration of two or more interspaces with excision of any grossly abnormal disks, and eight were treated conservatively without operation. In every case coming to operation the surgical findings coincided with discography for both normal and ruptured disks. There were no serious complications. Discography has not gained the recognition it deserves. The authors consider it probably more accurate than myelography in the verification and localization of disk herniations.

Effect of Stress Factors on Asthma in Guinea Pigs.—Asthma and other allergic manifestations are frequently relieved temporarily by febrile disease, localized infections, traumatic shock, surgical operations, and pregnancy. Attempts were made to duplicate some of these stresses by various types of fever therapy and fixation abscess, injections of various foreign proteins, and bacterial polysaccharides. In spite of the good clinical results obtained in asthma and other allergic conditions with cortisone and corticotropin, the majority of investigators have agreed that these hormones do not prevent anaphylactic death in the guinea pig. Need was felt for a method that would induce in guinea pigs a condition more closely resembling human asthma. The authors describe such a method in which asthma of controllable degree was produced in passively sensitized guinea pigs by the inhalation of aerosolized crystalline ovalbumin. Using this aerosol-induced asthma as an indicator, it was shown that a protective effect can be demonstrated by pretreatment of these animals with any of the following: tripelennamine (Pyribenzamine), cortisone, corticotropin, localized chemical inflammation, yeast suspension, sodium nucleate, and human serum. A pyrogenic bacterial polysaccharide failed to give significant protection. The method described and possible future modifications of it may be used advantageously in the study of basic factors in the production and alteration of hypersensitivity.

Renal Glycosuria.—The 38 cases of persistent nondiabetic glycosuria reviewed were detected in the course of physical examinations on 19,358 persons; most of them were students at the University of Minnesota and ranged in age from 17 to 37. Glycosuria was detected in 155 persons. All of these were called back for a repetition of the examination, a more complete history, and a glucose tolerance test of the two and one-half hour type with 100 gm. of glucose. These patients were examined between 1948 and 1952, and some could be followed for several years. Thirty-eight patients were found to have persistent recurrent glycosuria on a nondiabetic basis. Thirty-two of the 38 patients had fasting blood sugars that were normal (below 100), with normal curves and with transient urinary sugar. Six had a normal fasting blood sugar but an abnormally high peak curve, although with a return to normal and with a transient glycosuria. There were 32 cases of pseudorenal glycosuria and 6 of the possibly latent type of diabetes mellitus. The family history of the 38 patients revealed diabetes less often than is the case in patients with true diabetes. There was no tendency to obesity. The blood pressure range was normal. Fasting blood sugars were within normal range. The glucose tolerance curves were of two types: (1) the normal curve, with the peak generally under 150, but with sugar in the urine; (2) a high peak curve, with the upper reading over 180, and in some instances over 200. There was a return to normal or a hypoglycemic state within two and one-half hours, and glycosuria occurred. Three patients were given insulin, although the diagnosis of diabetes mellitus had not been verified by a glucose tolerance test. The author concludes that the dividing line between true renal glycosuria and pseudorenal glycosuria is less definite than is believed and that they probably are the same entity. There is an entity in which the span of the glucose tolerance curve is normal but the peak is high. This may possibly be explained by a slow, but adequate, islet cell response. It is necessary to rely upon an abnormal fasting blood sugar or a glucose tolerance curve in making a diagnosis of diabetes mellitus before starting treatment. Patients with glycosuria of any type must be followed up with sugar tolerance tests, in order to ascertain whether there is a change; each case presents an individual problem.

Cordotomy in the High Cervical Region for Intractable Pain.—French discusses the surgical relief of intractable pain arising in the region of the brachial plexus, the arm, the chest, or the upper abdomen. The operation consists of sectioning, in the region of the second cervical vertebra, the spinal cord tract carrying pain and temperature sensations, i. e., the lateral spinothalamic tract. High cervical cordotomy was performed on 42 patients. The group included patients with carcinoma in the breast, lung, esophagus, colon, pancreas, prostate, cervix, ovary, rectum, bladder, and kidney. Other patients had phantom limb, tabetic crises, and lymphatic leukemia. The pain was located in the middle or upper abdomen, in the chest, the arm, or the supraclavicular area. Where the primary lesion was in the pelvic organs, the neoplasm had extended into the pelvis and up into the retroperitoneal space. In 23 of the 42 patients the high cervical cordotomy was done unilaterally at the second cervical level. In 9 it was done bilaterally in the cervical levels, and in 10 the high cervical incision was combined with a contralateral incision in the upper thoracic level. The bilateral procedures were done for pain that was located either bilaterally or in the midline such as pancreatic pain or pain arising from metastases to the spine. Complete relief was obtained in 22 of 23 undergoing unilateral high cervical cordotomy, in 6 of 9 subjected to bilateral cervical cordotomy, and in 8 of 10 in whom unilateral high cervical cordotomy was combined with contralateral high thoracic cordotomy. Of the five fatalities two cannot be ascribed to the procedure. High cervical cordotomy has almost entirely replaced dorsal root rhizotomy except for pain in the upper four cervical segments. Complications appear to be less frequent than with thoracic cordotomy. There is less variation in the sensory levels obtained with the high cervical operation than with the high thoracic. It is believed that the lateral spinothalamic tract is more consistent in its anatomical structure and position at this level.

Otitis Media: Antibiotics Versus Surgery.—McLaurin believes that sulfonamides and antibiotics have been used indiscriminately in otitis media. These agents are capable of relieving the symptoms of otitis media but the pathological process may continue only partly or entirely unchecked. He saw 55 patients, chiefly children, with otitis media for which myringotomy was indicated. Thirty-four of the patients had had no previous treatment. They were all submitted to myringotomy, and they all recovered in an average of 5.17 days. The remaining 21 patients had all been treated previously by chemotherapeutic or antibiotic agents, without myringotomy. They sought medical relief because of continuing or recurrent infection. All were submitted to myringotomy, but their recovery took, on the average, 13.55 days. Furthermore, nine of them required the use of antibiotics, which were not employed until after their effectiveness against the organisms present had been proved in the laboratory. While the antibiotics usually relieve symptoms, they do not always eradicate infection, and they cannot restore the normal physiology in the presence of suppuration. Once middle ear disease is diagnosed, myringotomy is indicated under the following circumstances: severe and continuous pain; bulging of the tympanic membrane; loss or reduction of hearing in an acutely painful ear; a high septic temperature not otherwise accounted for; headaches and pain in the mastoid area; convulsions in infants; spontaneous perforation with evidence of inadequate drainage. Myringotomy should also be performed in all doubtful cases, whether or not the indications just listed are present. There is far less risk in incising the tympanic membrane unnecessarily than in allowing an undetected exudate to persist in the middle ear. The incidence of surgical mastoidectomy in otitis media has been materially reduced in recent years. Acute otitis media has itself decreased, a reduction which can be attributed to the use of the antibiotics in antecedent pneumonia and other severe respiratory infections.

Eosinophilia in Childhood Caused by Visceral Larva Migrans.—According to Dent and Carrera the term visceral larva migrans denotes the aimless migration of the larvae of certain round worms through the human viscera, although the particular species in question is not a parasite of man. The larval stage of nematodes usually parasitic in lower animals are capable of invading and damaging the human tissues and stimulating an eosinophilic response in the circulating blood. The condition is the visceral counterpart of the entity, cutaneous larva migrans, in which skin penetrating larvae of certain hookworms produce typical dermatological lesions. The authors obtained their knowledge of visceral larva migrans in part from seven clinical cases with two confirmatory liver biopsies and one complete autopsy, and in part from material submitted for consultation from three other cases in which a specific diagnosis has been established, and three additional cases in which the larvae have not been identified, but which showed typical histological lesions. In their experience, visceral larva migrans occurs in young children, usually from 18 months to 6 years of age—an age range within which children are most likely to swallow dirt. The symptoms are protean and consist of intermittent fever, malaise, pallor, loss of appetite, irritability, failure to gain weight, and muscle aches and pains. The children observed by the authors were "dirt-eaters," and there was close association with pets, especially dogs. When the cause of eosinophilia in children cannot be accounted for by allergy or orthodox parasites, one must consider the possibility of visceral larva migrans. The larvae of Toxocara canis, the ascarid of dogs, is probably the chief offender. Children become infected by swallowing dirt contaminated with feces of a worm-bearing dog. The larval parasites, after penetrating the intestinal mucosa, migrate through the organs and tissues, producing typical lesions and stimulating pronounced eosinophilia of the bone marrow and peripheral blood. Since these larvae do not complete their life cycle in man, an abnormal host for them, egg-laying adult worms of this species are not to be found in the human intestine; therefore the specific diagnosis cannot be made by fecal examination. Liver biopsy is at present the only means of establishing the exact diagnosis. As yet, no specific treatment is available. Awareness of the mode of infection, with adequate prophylaxis against subsequent exposures is the best form of therapy.

Biological Variability of Breast Carcinoma.—Medical writings as well as data prepared for the lay public generally imply that early diagnosis of breast carcinoma and radical mastectomy would result in an almost universal control of the disease. If this were so, there should be progressive local tumor growth and dissemination in a linear relationship to time, with surgical intervention representing the critical variable in relation to survival. Black and Speer show, however, that data in the literature as well as their own studies suggest the existence of biological variability in human breast carcinoma. It appears that variations in biological behavior within this disease are of far greater importance in determining survival than speed of diagnosis or surgical intervention. The five-year survival is invalid as a criterion of cure. Five-year survivals are not appreciably influenced by delays of weeks or months before surgical intervention. The majority of so-called operable cases of breast cancer have already undergone occult dissemination at the time of surgery. The curative effect of radical mastectomy probably does not exceed 10%. Ultraradical surgical interventions to cure breast cancer are not consistent with the biological nature of the disease.

Corticotropin, Cortisone, and Antibiotics in Overwhelming Infections.—Corticotropin and cortisone partially or completely suppress clinical manifestations of a wide variety of diseases resulting from specific infectious organisms. This suppression is not referable to inhibition of growth of the causative organism. Kinsell and associates state that corticotropin and cortisone have been administered over the past two years at their clinic to patients under reasonably well controlled conditions in an attempt to answer certain specific questions: 1. *Is there a place for the use of these hormones in management of patients with severe nontuberculous infectious disease?* 2. Is there any place for the use of corticotropin and cortisone in the treatment of patients with active tuberculosis? It was found that there appears to be a definite place for employment of corticotropin and cortisone, in conjunction with intensive antibiotic therapy, in the treatment of patients with infections of more than usual severity, i. e., infections that fail to respond adequately to chemotherapy alone. If hormonal therapy is to be used in such patients, it should be intensive initially, but should be decreased as rapidly as the patient's improvement permits. With the possible exception of tuberculous meningitis, corticotropin and cortisone are contraindicated in the presence of active clinical tuberculosis. This statement is subject to later revision. The use of diets high in protein and potassium, low in sodium and carbohydrate, and adequate in calories is imperative in all patients receiving corticotropin and cortisone.

Diabetic Myelopathy.—The reality of diabetic neuropathy without objective sensory loss became apparent to Garland and Taverner from clinical observation of the five patients whose case histories are presented. The youngest was 56 and the oldest 73. They all had diabetes of relatively short duration, varying from three years to six months. All complained of pain in the legs, which was always asymmetrical and sometimes unilateral. The pain, though diffuse, tended to be maximal in the hip and thigh. All showed wasting of the leg muscles and loss of the tendon reflexes in the legs. Four of the patients showed a high protein level in the cerebrospinal fluid. Electromyographic studies revealed changes, which seemed compatible with a myelopathic lesion. They are unlike the usual findings in peripheral neuritis. The authors feel that this is probably a form of diabetic neuropathy described by Bruns in 1890. Pathological studies were not possible on the present series of patients, but there were clinical features which suggested that the lesions may be present in their spinal cords. Not only was the disturbance limited to motor function but the distribution of the affected muscles was not compatible with the known distribution of peripheral nerves or nerve roots. The presence of extensor plantar responses in three, perhaps four, of the patients was unequivocal evidence of a central lesion. Whatever the nature and cause of the lesion in these patients, the authors felt that the existence of motor disturbances without objective sensory loss in diabetics, as described by Bruns over 60 years ago, was of clinical importance. These patients are being misdiagnosed as suffering from other, often more serious, neurological conditions. Treatment consisted of suitable diet, insulin treatment and physiotherapy. One patient continued to deteriorate for some months, but ultimately recovered completely. The oldest and least cooperative of the patients showed no change at the time of writing, four months after he was first seen; the other three improved rapidly after the institution of treatment. It seems possible that the natural history of this syndrome is one of spontaneous improvement, irrespective of the treatment employed.

Diabetic Neuropathy.—*Hirson and associates* found on routine examination of diabetic patients that neurological abnormalities were more the rule than the exception and that acute nervous diseases were by no means rare. They collected acute cases and examined a consecutive series of 100 diabetic outpatients. Of the 100 diabetic outpatients, 57 showed neural abnormalities and three had an acute neurological illness. To obtain more clinical information on acute neuritis in diabetes, the authors also studied 50 hospitalized diabetic patients. They found that about half of the patients with diabetes mellitus show evidence of neurological disease. They differentiate three types of diabetic neuropathy: First, the hyperglycemic form which is related to failure to control the diabetes and is rapidly relieved by proper treatment. The second is the active and most serious form of diabetic neuropathy, which is present in about 3% of diabetic patients; it is not related to the diabetic status and has a tendency to remission and relapse. The third form is asymptomatic and not disabling, but chronic and permanent. There is no evidence that arteriosclerosis or vitamin B_1 deficiency plays a part in the causation; the neuropathic process seems to be inherent in some cases of diabetes. Their observations support the view that diabetes is a disease-complex in which the metabolic disorder is only one manifestation, with neuropathy occurring not as a "complication" but as an integral part of a variable process. Sugar tolerance tests are of value in the investigation of obscure neurological disease. The production of gangrene, neurogenic bladder, and joint change by diabetic neuropathy is of practical importance.

The Intimal Ground Substance in Atherosclerosis.—According to Willis the mechanical stress important in the localization of atherosclerosis is a stretching of the arterial wall. This is *influenced by arterial blood* pressure, radius of lumen, curvature of artery and arterial fixation. This mechanical stress is counteracted by the components of the arterial wall. This stretching force may be linked with the stress which localizes lesions in scurvy. Because the primary changes in atherosclerosis are morphologically of the intimal ground substance at points of mechanical stress, Willis chose experimental scurvy as the ideal means of reproducing these conditions. A total of 145 guinea pigs was divided into the following dietary groups: (1) chronic scorbutic diet; (2) chronic scorbutic diet with oral ascorbic acid; (3) chronic scorbutic diet with cholesterol and oral ascorbic acid; (4) chronic scorbutic diet with cholesterol and intraperitoneal ascorbic acid; (5) acute scorbutic diet; (6) acute scorbutic diet with oral ascorbic acid; (7) acute scorbutic diet with cholesterol; and (8) acute scorbutic diet with oral ascorbic acid and cholesterol. It was found that ascorbic acid deficiency in guinea pigs produces atherosclerosis regardless of whether the scurvy is acute or chronic. Atherosclerosis of scurvy occurs at normal cholesterol levels and without deposits of lipid in the reticuloendothelial system. This form of atherosclerosis thus closely simulates the human form of the disease. Intraperitoneal ascorbic acid greatly inhibits atherosclerosis of cholesterol feeding in guinea pigs. The ground substance disturbance associated with atherosclerosis is of major importance in the pathogenesis of arterial calcification, intimal hemorrhage, and thrombosis. Cholesterol feeding interferes with ascorbic acid metabolism in rabbits and in guinea pigs receiving oral ascorbic acid. Acute infection in guinea pigs produces minimal atherosclerosis in about 33% of guinea pigs studied. Thyroid and cortisone have no inhibitory effect on the atherosclerosis of cholesterol feeding in guinea pigs in a small series nor do they inhibit the atherosclerosis of scurvy. Massive parenteral doses of ascorbic acid may be of therapeutic value in the treatment of atherosclerosis and the prevention of intimal hemorrhage and of thrombosis.

Complications of Gold Therapy: Effects of Splenectomy and Dimercaprol (BAL).—Watson points out that of the complications associated with the therapeutic use of gold salts, those affecting the hemopoietic system are the most critical. They comprise thrombocytopenia, granulocytopenia, hypoplastic or aplastic anemia, occurring singly or in various combinations including pancytopenia. The manner by which the compounds of gold effect these several blood dyscrasias is debatable, but it is not inconceivable that they may act upon the spleen, initiating in some unknown manner a disturbance of its functions. By virtue of this conception the blood dyscrasias related to gold may be regarded pathogenetically as falling within the realm of secondary hypersplenism. A case of pancytopenia and two cases of thrombocytopenic purpura developing after the use of gold preparations are cited. In two of these, clinical and hematological improvement followed splenectomy. The administration of dimercaprol (BAL) to one patient failed to influence the thrombocytopenia.

Mumps Meningoencephalitis.—An epidemic of mumps occurred between December, 1951, and June, 1952, in a rural area of Saskatchewan and gave Bowers and Weatherhead an opportunity to study this disease. They estimate that about 250 cases of mumps occurred among a population of 3,500, this being the first epidemic in the locality since 1937. While the authors did not see all of the cases, they feel that most of those taking an atypical course were reported to them. A diagnosis of manifest mumps meningoencephalitis was established in 39 cases. Descriptions of the illness by telephone during the acute phase, and in personal interviews after recovery, convinced them that many additional cases of mumps meningoencephalitis occurred. The authors conclude that about 25% of all persons with mumps may be expected to manifest mumps meningoencephalitis. The authors believe that more frequent spinal fluid examination would demonstrate that many such patients have mumps meningoencephalitis. Mumps meningoencephalitis must be thought of in the diagnosis of all patients presenting with an acute viral disease of the central nervous system, even in the absence of a recent salivary gland or testicular enlargement. No specific therapeutic agent is available. Acetylsalicylic acid relieved many of the headaches, and with careful nursing supervision controlled the fevers. Dimenhydrinate proved of some value in arresting vomiting. Parenteral rehydration was required by several patients. In many instances the initial diagnostic lumbar puncture appeared to relieve distress. Repeated spinal drainage seemed of no avail. Initially, the authors attempted to insist on hospitalization until the spinal fluid cell count returned to normal. As the epidemic spread it was found that a patient could improve clinically while the spinal fluid cell count rose, and that of two patients, the sicker might have the lower cell count. For these reasons, repeated cell counts were discontinued, and patients were discharged for convalescence at home 48 hours after the temperature had become normal.

Vascular Murmurs and Peripheral Circulatory Disturbances.—Holldack and Kuhn examined patients for murmurs in the large vessels. Frequently when there were other signs of peripheral circulatory disturbances, they found murmurs in the large vessels. Murmurs cannot be produced by compression of the abdominal aorta because its mobility is such that it cannot be compressed. To detect the vascular murmurs the stethoscope is pressed deeply into the abdomen. The "knocking tone," which is occasionally audible above these vessels, is readily differentiable from a murmur. In the presence of very thick abdominal walls the murmur may be very soft, and careful search is required, particularly if the intestinal peristalsis is loud. Studies on more than 1,000 persons revealed that in persons with a sound vascular system murmurs were never perceptible above the aorta or its two main branches, the iliac arteries. In patients with intermittent claudication or with other disturbances in the peripheral circulation murmurs are frequently detected over these vessels. The objection might be made that the aortic murmurs above the umbilicus are transmitted cardiac murmurs, because in this region the heart sounds are still audible. For this reason the authors made phonoangiographic records of the vascular murmurs, which revealed that these murmurs appear later than the heart sounds. Vascular murmurs were also occasionally perceptible in the carotid arteries in a patient with severe cerebral sclerosis, but generally murmurs are missing in the carotid arteries, even if sclerosis in this vascular region is severe. Auscultation of the aorta and iliac arteries and phonoangiographic registrations convinced the authors that these simple methods of examination provide information about pathological changes in the vascular walls. The absence of vascular murmurs does not necessarily prove that a vessel is normal, for completely obstructed vessels likewise do not produce murmurs and not all diseased vessels necessarily produce murmurs. The vascular auscultation method should be employed only in connection with other methods of examination. Vascular murmurs can be recorded at one or several sites in about 75% of patients with impaired peripheral circulation. The number of patients with disturbances in the peripheral circulation, obliterating endangiitis, or arteriosclerosis studied by the authors has now reached 48, and the frequency with which vascular murmurs were detected has remained about the same (75%).

Question of Tuberculous Etiology of Sarcoid of Boeck.—Doepfmer reports studies on 12 patients with Boeck's sarcoid, in whom the diagnosis was established by repeated clinical observation, histological studies, and roentgenologic findings. Animal experiments were made on guinea pigs, and excised specimens were cultured in Hohn's egg medium. Some of these patients had been observed for several years, and exploratory excisions had been taken for animal tests. Other patients had fresh foci in which presumably tubercle bacilli could be demonstrated only by the Kyrle method. Two animals were used for each investigation. In one test the biopsy specimen was cut up and dismembered by crushing it in a mortar in isotonic sodium chloride solution, and the suspension injected into the knee fold of one animal;

in the other animal, a piece of the biopsy specimen was implanted. Four weeks later the animals were tested with tuberculin. The animals were killed after three months and necropsy material obtained for subsequent passages from the regional lymph nodes and from suspensions of spleen or liver. Six passages were made in six patients with sarcoid of Boeck. In four patients three passages were made, and in three patients, so far, two passages. No indication of the presence of tuberculosis was obtained in any of these tests. None of the animals gave a positive tuberculin reaction. In further tests the tuberculosis complement fixation test was performed with tuberculosis antigen on patients with sarcoid of Boeck, on healthy subjects, and on patients with skin tuberculosis or scrofuloderma. Positive reactions were obtained in a small percentage of patients with sarcoid of Boeck, but some of the healthy subjects also had positive reactions, whereas only about two-thirds of the patients with lupus or scrofuloderma had positive reactions. The authors feel that these results do not prove a tuberculous etiology in sarcoid of Boeck.

Streptokinase and Streptodornase in Enzymatic Decortication.—Halse and Braun review the status of knowledge on the enzyme systems of the body which under physiological conditions liquefy fibrin not only intravascularly but also extravascularly. The fact that blood remains fluid in the large body cavities can be traced to the process of "decoagulation." Hematomas, hemarthrosis, or hemothorax can be evacuated only after this process has taken place. The fibrinolytic process represents a very sensitive enzymatic system which is easily impaired. Hemolytic streptococci produce an activator of fibrinolysin, known as streptokinase, and thereby are able to liquefy the fibrin membrane which is formed by the organism. Streptokinase can be used to accelerate the retarded "decoagulation." The penetration of streptokinase is facilitated by streptodornase, a true ferment or enzyme which is capable of breaking down the chief constituent of abscess membranes and of pus, namely desoxyribonucleoproteid. On the basis of viscosity determinations and of microphotograms examples are given to illustrate liquefaction of pus by means of streptodornase. The authors report their clinical experiences, which corroborate the observations of American authors on the therapeutic use of streptokinase and streptodornase in the treatment of septic surgical lesions. Repeated irrigations with these enzymes effected complete enzymatic decortication in 17 patients with residual osteomyelitic cavities. In eight cases considerable improvement resulted, whereas in three cases no result was obtained. Favorable results were also obtained in local treatment of superficial necrosis, chronic abscesses, pleural empyemas, and fistulas. In a total of 92 patients the results obtained were excellent in 59 and satisfactory in 21, whereas in 12 no influence could be observed. There were no undesirable secondary effects.

Acute Thyroiditis.—The authors report three cases of acute nonsuppurating thyroiditis. The patients were a boy, 17 years old, and two women, 42 and 64 years of age. In the first patient fluctuation of the thyroid was palpated. The exploratory puncture gave negative results. The disease was controlled by penicillin alone in doses of 100,000 units every four hours for four consecutive days. Upon discontinuation of the treatment for four days the disease reappeared, proved to be resistant to penicillin, and was controlled by the combined treatment with penicillin, sulfadiazine, and short waves. In the second patient the condition was caused by the infection of the maxillary and facial sinuses. Both sinusitis and thyroiditis were controlled by the treatment with penicillin, sulfadiazine, and local application of short waves. In the third patient the disease was due to infectious tonsillitis. The combined treatment given for 10 consecutive days was ineffective. Cure was obtained after tonsillectomy. The patients are well three to three and one-half years after the treatment. The author advises the use of penicillin alone, when penicillin-sensitive micro-organisms can be identified as cause of the infection. Short waves applied to the thyroid are of value in the treatment. Surgical therapy should be restricted to cases of suppurating thyroiditis or to cases in which acute complications of thyroiditis occur, such as mediastinitis, edema of the larynx, pressure upon the trachea and rupture of an abscess into an adjacent region; all of these require immediate surgical intervention.

Headache and Hypertension.—Persons with hypertension often complain of headache, dizziness, shortness of breath, or even of losing their tempers. It does not follow, however, that the blood pressure is to blame. In a survey of 200 consecutive patients with severe hypertension an assessment was made of the symptom of headache by an interrogation technique designed to avoid suggestion. Patients who were aware and those who were unaware of their hypertension were compared. The severity of the hypertension was found to be about the same in the two groups as regards the diastolic level, electrocardiograms, and roentgenologic appearance of the left ventricle. Retinal changes were somewhat greater in those with headache. Of 104 patients unaware of their hypertension, 87 would not admit to having headache. This tendency for headache to be absent persisted through all grades of diastolic pressure. Only three of these patients stated spontaneously that they had headache and 14 others admitted they had headache on questioning. Of 96 patients who were aware of their hypertension, 71 complained of headache, most of them in terms characteristic of anxiety. Analysis of the remaining 25 revealed that 18 had organic cause of complaining of something else and 6 offered symptoms characteristic of anxiety. From these observations together with evidence obtained from the examination of controls Stewart concludes that the headache which so often accompanies hypertension is usually a product of anxiety. It seems almost impossible for a patient who has been told of his "blood pressure" to remain free of symptoms. It appeared that hypertension might occasionally produce headache as an organic symptom. This was most likely in menopausal women during the early stages of benign hypertension, or, as a relatively insignificant feature, within the syndrome of malignant hypertension. It is a fallacy to acclaim any treatment of hypertension in virtue of its alleged cure of headache.

Poliomyelitis Following Inoculation.—Geffen and associates cite previous reports on the association between immunization and paralytic poliomyelitis, calling particular attention to Geffen's own report in 1950. Reference was made to 37 children, of whom 30 had developed poliomyelitis within a month of immunization, the site of paralysis being the site of injection. None of these subsequently died, and 27 of these 30 children were examined some two years later. Hospital records of the illness and present condition were available of two of the other three children. The extent of the recovery in these 29 children was compared with that of another 23 children who had not had any recent injection but who had poliomyelitis at about the same time in London in 1949, who were of approximately the same age, and in 21 of whom an upper limb was one of the limbs affected. The average interval between inoculation and the onset of poliomyelitis was 13 or 14 days: in over 80% of cases it was between 5 and 16 days. It is probable that three weeks after inoculation the period of risk has passed. The preparalytic symptoms recorded in the 29 inoculated children were in the main similar to those observed in the controls. The paralysis of poliomyelitis following recent inoculation appears to be relatively limited in extent, but it is nearly always severe. Recovery of the limb appears to depend on the initial severity of the paralysis, irrespective of whether the limb has been inoculated or not. The extent of recovery which took place in two and a half years in both the inoculated and control groups was related to the severity of the original paralysis. In the 29 inoculated children there was no information that the inoculations were intramuscular rather than subcutaneous. It is considered doubtful if immunization at an earlier age would prove effective in avoiding post-inoculation poliomyelitis. It has not been proved that lay publicity on post-inoculation poliomyelitis is the reason for recent reduction in the number of children immunized against diphtheria. The authors are of the opinion that the public is entitled to have the facts put before them clearly.

Salvioli's Diffusing Vaccine for Antituberculous Vaccination.—Salvioli's diffusing vaccine (V. D. S.) for immunization against tuberculosis consists of killed human and bovine tubercle bacilli combined with hyaluronidase. It is prepared by suspending 3.75 mg. of Koch's bacilli in 1 cc. of isotonic sodium chloride solution and heating the suspension to 100 C for 10 minutes. The suspension is returned to laboratory temperature, and hyaluronidase is added to it in the ratio of 30 viscosity units to 1 cc. This preparation is placed in 0.2 cc. or 1 cc. ampuls, which are then lyophilized. At the time of the vaccination water is added in an amount equal to that which was removed by the lyophilization process. The 0.2 cc. ampul contains 0.75 mg. of killed bacteria and 6 viscosity units of hyaluronidase. It is the effective dose for a newborn infant or a nonallergic infant less than one year old. Half of this ampul is sufficient for one school age child or one adult. The 1 cc. ampul thus contains enough preparation to vaccinate 5 newborn infants or 10 adults. The best location for the vaccination is the inner aspect of the forearm, and the intradermal route has proved to be the best way of administration. The vaccinal focus manifests itself as a small swelling that lasts from two to four months. The second phase of the inflammatory process is characterized by a reactivation of the focus during which the swelling becomes more pronounced, a small eschar is produced, and in many instances there is interstitial exudation and necrotic phenomena in the outer layer of the skin. Later a crust is formed and then a scar. Salvioli studied 334 persons, 6, 12, and 18 months after they had been vaccinated with this vaccine. An allergic state was present in all newborn infants and all adults (up to 18 years of age) 18 months after the vaccination. All of these persons had had a patent vaccinal reaction. Allergization had been secured, however, in only 85 to 90% of the children between the age of 4 and 6 years. There was no patent reaction in some of these, but a slight depression of the skin in the area where the vaccine was injected indicated that the reaction was taking place in the hypoderm. A focus did not appear in 16 of these 40 children and in 3 of them the allergic state had not been secured 18 months after the vaccination. The same dose of vaccine (0.37 mg. of killed bacteria and 3 viscosity units of hyaluronidase) was used for these children as for the older ones. But since the reaction to this vaccine is more pronounced in older children, the author ascribes these inconstant results to an insufficient dose of vaccine. A dose which will produce the allergic state in all children between 4 and 6 years of age has not as yet been established.

Streptomycin in Spinal Fluid of Patients with Tuberculous Meningitis.—Studies were made to determine the factors which may influence the amount of streptomycin present in the cerebrospinal fluid of patients with tuberculous meningitis treated with this antibiotic. Hypotheses were advanced that there could be some enzymatic action on the antibiotic due to the presence of bacterial catabolic products in the fluid itself, pathological tubercle products in the specific meningeal lesion, or proteins of blood origin produced by alterations in the hematoencephalic barrier. In the first study patients with the disease who were being treated with streptomycin were not given the antibiotic for 24 hours and 2 to 3 cc. of spinal fluid were removed from each patient. Then 1 cc. of the fluid was added to a streptomycin solution so that 1 cc. of the resulting solution contained 40 mcg. of the antibiotic. This was also added to 1 cc. of isotonic sodium chloride solution in the same ratio and both solutions with the remaining spinal fluid were placed in a thermostat at 37 C. After eight hours there was no antibiotic in the cerebrospinal fluid whereas there were still 40 mcg. of streptomycin in each of the other two solutions. Thus there was no substance in the fluid of these patients that inhibited even partially the antibiotic. The author then studied the eventual influence of the meningeal permeability on the presence of the antibiotic in the fluid of other patients. He made the study on 14 patients, of whom 12 had tuberculous meningitis and had been receiving the drug for varying periods. The renal function was not impaired in any of them. After a treatment-free period of several days, each patient was given 0.75 mg. of streptomycin per kilogram of body weight intrathecally. The urine was collected and blood specimens taken four and eight hours later, while cerebrospinal specimens were taken eight hours later by the suboccipital and the lumbar routes. He found that the antibiotic escapes rapidly from the spinal fluid of patients in whom the disease is of recent onset. This is ascribed to hypersecretion of the choroid plexuses, and therefore hypertension of the fluid, while the pathways of drainage are not impaired by the disease. Patients in whom the disease is of long standing retain the antibiotic in the lumbar space when a complete or partial block develops and in the leptomeningeal space when there are alterations of the pacchionian bodies. The retention of streptomycin in the spinal fluid may also be caused by sclerosis and calcification of the plexuses. These alter the vasomotor and secreting sympathetic fibers and thus cause changes in the production of ventricular fluid; a decreased ventricular secretion of the subarachnoid spaces retards the drainage of the fluid and therefore of the antibiotic. Another possibility is the occurrence of biochemical changes in the meningeal collagen tissue, as happens in meningeal inflammation of long duration, with a consequent reduction of the meningeal permeability. A definitive evaluation is not possible yet. The varying levels of streptomycin in the cerebrospinal fluid of patients with tuberculous meningitis are due to a greater or lesser permeability of the hematoencephalic barriers, and also to the various mechanisms which influence directly or indirectly secretion, circulation, and drainage of the cerebrospinal fluid.

Epidural Space in Polyradiculitis (Landry-Guillain-Barré Syndrome): Spinal Peripachymeningitis.—In the first of the four cases of polyradiculitis reported death from respiratory paralysis occurred on the 13th day; interstitial round cell infiltration was found in the peridural adipose tissue. In the third and mild case, where the patient was improving rapidly, pulmonary embolism caused sudden death five weeks after the onset; microscopic examination revealed slight changes corresponding to the mild nature of the disease. In the second case, with death from respiratory paralysis and circulatory collapse after four weeks, the cerebrospinal fluid was yellowish, with greatly increased albumin content. The degeneration of peripheral nerves and spinal cord was pronounced. Antoni believes that with the extensive and marked paralysis, intact anterior roots and strongly degenerated posterior roots the lesion must have been extradural. The degeneration of the posterior root system is secondary or wallerian. In the cervical, dorsal and lumbosacral region the epidural tissue showed an irregular disseminated intensive round cell infiltration, partly perivascular, in places with hemorrhages. Adipose infiltration of this kind might explain the pronounced hyperemia of the intradural structures, the increased albumin content of the cerebrospinal fluid and the mainly secondary character of the histologic changes revealed in the peripheral nerves, spinal roots and spinal cord. In the fourth case, clinically diagnosed as spinal peripachymeningitis in the middle thoracic region, chest roentgenograms showed left basal bronchopneumonia. Penicillin treatment resulted in rapid improvement and recovery.

*Study of 47 Strains of Koch's Bacillus Isolated During Primary Tuberculous Infection in the Child: Their Sensitivity to Streptomycin and Their Species. A. Bertoye, J. Viallier, P. Gallois and L. Delaruelle.—p. 485.
How to Consider the Etiology and Pathogenesis of Rhinobronchorrhea and Bronchiectasis in Infancy. Arguments Drawn From 298 Cases. M. Roche.—p. 491.

Study of Many Strains of Koch's Bacillus.—Koch's bacilli obtained from children with primary tuberculosis were studied in relation to their sensitivity to streptomycin and their species. Specimens, obtained by gastric washing and guinea-pig inoculation, consisted of 40 strains isolated before, and seven strains isolated during treatment with streptomycin. The limit of therapeutic efficiency is usually set at a level of 10 mcg. per cc.; of the 40 strains isolated before treatment, all were sensitive to streptomycin, only two requiring as much as 10 mcg. for their inhibition. Indications for streptomycin in primary infection are limited, and bacilli are not often found in gastric washings after streptomycin therapy has been started; consequently, the number of strains isolated during treatment was small, but of the seven found, six were sensitive to concentrations of 1 mcg. and only one required 10 mcg. for inhibition. The age of the children, all of whom were less than 3 years old, and the noncavitary form of the disease were apparently important factors in the continued streptomycin sensitivity of the bacilli; combined therapy, which delays the appearance of streptomycin resistance, had been given to only two of the seven children. None of the 47 strains examined belonged to the bovine variety of M. tuberculosis, although certain factors usually taken to indicate a bovine origin for the disease, such as the onset of illness during vacations in the country and the drinking of raw milk, were present in several cases. The nonexistence of streptomycin-resistant bacilli in the untreated children and the nonappearance of resistant strains in children under 3 subjected to streptomycin therapy are in marked contrast to the conditions found in adults.

One Year of Antituberculous Therapy with Isoniazid: Observations and Comments. B. Boggian.—p. 748.

Study of Influenza Epidemic of 1952-1953 in the Rome Area.—Approximately 300 persons were treated by the authors during the influenza epidemic which occurred in the Rome area during the winter 1952-1953. The first cases were reported in the latter half of December in persons living in the vicinity of the International Airport of Ciampino (Rome). An outbreak had been previously reported at the beginning of the same month in the United States in the state of Missouri and simultaneously in Tokyo. These might have been the initial foci from where the epidemic spread. The course of the disease in the authors' patients was typical, with a sudden onset, chills, indisposition, pain in the muscles and joints, headache, cough, and elevated temperature. The only atypical symptom was vomiting, which appeared on the first or second day of the illness and lasted no longer than 24 hours. It had all the characteristics of a cerebral vomiting, probably of toxic pathogenesis. Besides tracheobronchitis, there was involvement of the Eustachian tube, middle ear, and paranasal sinuses, especially during the later period of the epidemic. Studies on the blood serum of 72 patients indicated that an A′ virus was responsible for the epidemic. The throat washings of 10 patients were inoculated in embryonated eggs, and two strains of virus were isolated. According to the authors and the World Influenza Center in London, these strains resembled closely the 1950-1951 Scandinavian type. They were called A-Rome (1-53) and A-Rome (7-53).

Practical Utilization of ACTH by the Intramuscular Route in Combination with Depot-Penicillin. E. Aron and R. Lecomte.—p. 811.

Effect of Pyrazol Derivatives on Serofibrinous Pleurisy and Pulmonary Tuberculosis.—The mediocre results obtained with antibiotics in patients with tuberculous serofibrinous pleurisy prompted a trial of anti-inflammatory substances. A combination of phenylbutazone and aminopyrine in equal quantities, known in Europe as Irgapyrin and in America as Butapyrin, was used first; later, the second derivative, phenylbutazone (Butazolidin), was used alone. Fever disappeared rapidly in all the pleuritic patients treated with these drugs and they obtained pronounced relief of pain and dyspnea. Similarly good results were secured in patients with pleurisy complicated by pulmonary lesions; even patients with pulmonary tuberculosis who were virtually in extremis when brought to the hospital became less fatigued and dyspneic after receiving the drugs. The effect of the pyrazol derivatives was seen chiefly in the general condition; the temperature fell rapidly, sometimes to 36 or 35 C, and this decline was accompanied by a feeling of relief, cessation of chills and malaise, and improvement of the functional symptoms. Physical signs, on the other hand, were unchanged and the course of the pleural process was apparently unaltered. The beneficial effect of the drugs seems to be the result of their anti-inflammatory and anticongestive action, and this fact may well lead to a reconsideration of the significance of general inflammatory phenomena in the development of pulmonary tuberculosis. Recognition of the antalgesic effect of the pyrazol derivatives in numerous disorders is increasing; the rapid relief they afford in pleurisy and severe tuberculosis makes their prompt administration to patients with these conditions advisable.

Radioactive Iodine Treatment in Hyperthyroidism.—I^{131} is the treatment of choice in all cases of hyperthyroidism in which surgical procedures are contraindicated. Improvement does not usually become apparent until one month after ingestion of the therapeutic dose, and a definitive estimate of the results of treatment cannot be made before the end of three months because the patient's condition may continue to improve throughout that period, and even afterwards in some cases. Adequate quantities of I^{131} first became available to the French in 1949; since then, 115 hyperthyroid patients, almost all of whom were ambulatory, have been treated at the Hôpital Necker and the Institut Gustave-Roussy, with excellent results in 66%, moderate results in 18%, and failure in 11%. Continued improvement under therapy in some patients or possible relapses in others may lead to revision of these figures. I^{131} is easily administered and free from immediate danger, but it should not be given to patients under 40 because of the possible late development of radiation injury. Pregnancy is an absolute contraindication to its use. It is well tolerated, even by patients in poor general condition and those with thyroid heart disease; some of the patients in this series gained from 20 to 40 kg. in weight and were enabled to resume a normal life. I^{131} acts by reducing the functional activity of the thyroid tissue; its effects resemble those of subtotal thyroidectomy, but the reduction in thyroid function is more gradual.

Corticotropin in Trichinosis.—Corticotropin (ACTH) and cortisone rapidly control fever and symptoms of trichinosis. Only three reports on the good results of these drugs in five cases have been reported in the literature. The authors gave corticotropin to eight patients in the acute stage of the typical disease with hyperleukocytosis, hypereosinophilia, and a strongly positive diazo reaction in the urine. The drug was given in an average daily dose of 60 mg. up to a total dose of from 180 to 980 mg. in from 3 and 18 days. The results were spectacular. Fever, dyspnea, muscular pain, stiffness and the nervous symptoms were controlled within 24 hours. The white blood cell count became normal, eosinophilia disappeared, and the diazo reaction in the urine became negative in some cases but not in all. Discontinuation of the treatment caused reappearance of the disease in one patient, although with milder symptoms. The disease was controlled by further administration of the drug for one week or 12 days. Cortisone was given to a patient for two days in a total dose of 500 mg. without effect. The authors believe that trichinosis is due to an allergic inflammatory reaction of the tissues which is favorably modified or controlled by corticotropin. The tissue reaction lasts as long as the parasites have not reached the phase of encystment which marks the period of asymptomatic latency of the disease. The diazo reaction in the urine is positive in the allergic phase and negative in the phase of encystment. The treatment should be continued until a negative diazo reaction in the urine is obtained.

Patients with Heart Disease. R. Siebeck.—p. 507.
*Loss of Hair After Anticoagulant Therapy. R. Fischer, J. Bircher and T. Reich.—p. 509.
Studies on Problem of Goiter: V. Structure of Goiter and Types of Goiter; Experimental Study. F. Blum.—p. 513.

Loss of Hair After Anticoagulant Therapy.—The authors examined 87 patients who six months to two years previously received anticoagulant therapy. Eleven patients had been treated with a synthetic heparin preparation (Thrombocoid), 25 with bishydroxycoumarin (Dicumarol), 11 with ethyl biscoumacetate (Tromexan ethylacetate), and 40 with pure heparin (Liquemin) or synthetic heparin followed by bishydroxycoumarin or ethyl biscoumacetate. Loss of hair took place in 5 (45%) of the patients treated with synthetic heparin alone, in 11 (44%) treated with bishydroxycoumarin alone, in 4 (36%) treated with ethyl biscoumacetate alone, and in 31 (78%) treated with heparin and coumarin preparations. The loss of hair was noted after an average latent period of eight weeks and continued for about six weeks on the average. The duration of the anticoagulant therapy and the age of the patients did not play a significant part. The incidence of loss of hair was relatively higher in women. The loss of hair was diffuse, similar to that of symptomatic diffuse alopecia after thallium poisoning or severe toxic conditions. Ten of the authors' patients had been given various proprietary vitamin preparations, such as vitamin C (Redoxon), a mixture of vitamin B_1 and acetylcholine chloride (Benerva), and vitamin B_1, B_2 and B_6 (Becozym) simultaneously with the anticoagulants, but the loss of hair was not affected by this combined treatment. The prognosis of the condition is favorable since growth of hair recurred in all patients except for two men in the families of whom other cases of alopecia occurred. Treatment of loss of hair is only of psychological value. At present no drug is known that could prevent the loss of hair.

Thornell's Operation in Bilateral Paralysis of Recurrent Nerve. J. C. Nielsen.—p. 855.

Renal Osteodystrophy.—Dragsted and Hjorth discuss the different forms of renal rachitis and osteomalacia. Based on pathogenesis and clinical symptoms, a distinction is made between renal osteomalacia due to glomerular affection and that due to tubular affection. The bone disorder of the first group depends on acidosis in combination with phosphate retention. Roentgenologically it is manifested as an osteitis fibrosa cystica. Bone disorders of the second group are partly congenital and depend on reduced phosphate reabsorption in the tubuli; the glomerulus function is normal. The lowered phosphate reabsorption may be combined with reduced reabsorption of glucose, amino acid, potassium, water and with disturbances in the renal regulation of the acid-base equilibrium of the organism. In adults the symptoms are osteomalacia, possibly with Milkman fractures, and in children, dwarf growth. The characteristic changes in blood chemistry are low serum phosphorus and increased alkaline phosphatase. In cases accompanied by disturbances in acid-base regulation there is hyperchloremic acidosis. Treatment consists in administration of vitamin D in doses up to 500,000 units daily together with calcium phosphate, under control of the serum calcium and serum phosphorus, and in cases with acidosis, correction of this with sodium citrate.

Improved Results in Treatment of Bronchogenic Cancer.—Hansen and Kjaer's material consists of 638 consecutive cases of verified primary bronchogenic cancer treated from 1944 to July, 1952. During the first three years resection could be successfully carried out in only 8.1% of the cases: now the percentage is 41.6. During the first five pneumonectomy was necessary in 88.1% of the resectable cases; in 1951-1952 pneumonectomy was done in 59.4%, bilobectomy in 9.4%, lobectomy in 20.8%, and segmental resection in 10.4%. The mortality in hospital and during the first two weeks after discharge has been about constant, around 25%. It is twice as high in pneumonectomy as in smaller resections. Increased attentiveness of physicians and patients to early symptoms of cancer of the lungs and more frequent intensive examination of all cancer suspect pulmonary diseases together with cooperation with the central tuberculosis station have contributed to the progress in the fight against cancer of the lungs.

BOOK REVIEWS

A Handbook of Radiotherapy. By Walter M. Levitt, M.D., F.R.C.P., F.F.R., Associate Physician to Department of Radiotherapy, St. Bartholomew's Hospital, London. Cloth. $6.50. Pp. 232, with 53 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1952.

The author, an experienced radiotherapist, has compressed most of the essentials of radiotherapy into a small book. In such a concentrated presentation it is necessary to pick and choose, especially when traversing growing and changing fields, but the philosophy and the technique outlined here have as wide and well-founded an acceptance as any that could be presented. The first three chapters are devoted to radiation physics and apparatus. Next are two chapters on radiobiology and its clinical relationships. Chapter 6 covers the management of the patient receiving radiation. The remainder of the text presents the principles of management and of treatment technique in malignant, and some benign, diseases, with a chapter devoted to each of the anatomic areas or systems of radiotherapeutic interest. The illustrations are well chosen diagrams, photographs, and radiographs. One appendix is a summary of the Portmann classification of breast carcinoma and of the League of Nations classification of uterine cervix carcinoma. A second appendix is an abstract of the International Recommendations on Radiological Protection (Sixth International Congress, 1950). There is an adequate index and a small bibliography of limited value.

The author has confined his discussion closely to radiation therapy, so closely, in fact, that no mention is made of the mustard compounds in the treatment of the malignant lymphomas, or of hormones in breast cancer. On the other hand, surgery, when the primary, alternative, or supplementary treatment, is adequately presented in its proper perspective. Mention of the artificial radioisotopes is confined to the clinically established P^{32} and I^{131}. They are presented as part of the general discussion of the treatment of those diseases in which they are of value. One short paragraph about metastatic tumor deposits in bone does not give the subject quite the consideration it warrants. The book is practical rather than theoretical. It is too concise for the unaided novice in the field. It is well adapted to the needs of the postgraduate student and to the general practitioner of radiology.

A Treatise on Hygiene and Public Health with Special Reference to the Tropics. By Birendra Nath Ghosh, F.R.F.P.&S., F.R.S. Thirteenth edition. Cloth. Rs. 17/8; 25s. 6d. Pp. 787, with 151 illustrations. Scientific Publishing Co., 85, Netaji Subhas Road, Calcutta-1, 1953.

The fact that this textbook is now in its 13th edition is ample evidence of its value and popularity. The author possesses Scottish fellowship qualifications and is well acquainted with the topics traditionally taught in courses of hygiene and public health in the universities and institutes of public health in the United Kingdom. Revision of the text necessitated the rewriting of certain sections and the adding of others. The text is profusely illustrated with diagrams, photographic reproductions, and tables. Much of the text appears in smaller type than the ordinary reading type, and thus a compendium of detailed information is compressed into small bulk, a veritable *multum in parvo*. The greater part of the book is taken up with environmental hygiene, discussing such subjects as water and water supply, air and ventilation, the soil and its formation, housing, disposal of refuse and human excreta, sewage disposal, climate and meteorology, village sanitation, sanitation of fairs and religious festivals, and camp sanitation. These chapters reflect the state of the public health in an overpopulated country like India. The chapters on food, diet, and vegetable and animal foods contain frequent references to conditions in India. The statement (page 225) that flash pasteurization of milk does not give a satisfactory result is unacceptable.

There are interesting chapters on mental hygiene, maternity and child welfare, medical inspection of schools, infection and carriers of infection, animal parasites, epidemiology and preventable diseases, and vital statistics and statistical methods. The final chapter deals with social medicine but is rather disappointing, as it appears to confuse social medicine with socialized medicine. Ryle's concept might have been more explicitly outlined and examples quoted. The illustrations of the insect vectors of disease in chapter 21 would be improved by an indication of size. The newer knowledge of the exoerythrocytic cycle of the malaria parasite in chapter 24 is described, but the schematic representation of the life cycle would have benefited by a color plate. The technique of performing the Schick test (with control) and the reading and interpretation of the tests should have been more carefully described. Recent work has shown that 1/100 to 1/250 unit is a more probable level of diphtheria antitoxin per milliliter of blood serum than 1/30 unit in a negative Schick test. The text suffers from blemishes in frequent errors in spelling and in terminology and could not be recommended for medical students in North American universities.

Essential Urology. By Fletcher H. Colby, M.D., Chief of Urological Service, Massachusetts General Hospital, Boston. Second edition. Cloth. $8. Pp. 650, with 352 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

It is refreshing to read this excellent book. The volume has been designed for use by medical students, residents in urology, practicing urologists, and general practitioners. The text is divided into three parts. The first portion includes the embryology, anatomy, and physiology of the genitourinary organs. The second division deals with the examination of the urologic patient. The last, and largest, section embraces a comprehensive discussion of the diseases of the genitourinary tract. The book contains eight charts. The figures are composed of urograms, anatomic drawings, photographs, and photomicrographs. The bibliography is recent, relevant, and critically selected.

The author states that his objective is "to give the important facts of embryology, anatomy, physiology, and diseases of the genitourinary organs." The preceding statement is a key to the reason for the outstanding quality of this book. Unlike many works in the field of medicine this book is largely based upon sound experimental evidence and not on clinical impressions. The author is to be commended for his ability to separate the "wheat from the chaff." The material is presented in a uniform and lucid style. It is believed that the text could be improved in some respects; for example, in the section on examination of the urological patient, greater emphasis should have been placed on the significance of hematuria and the type of examination almost invariably required when this sign appears. This book is highly recommended to students, residents, urologists, and practitioners of medicine in general.

The 1952 Year Book of Obstetrics and Gynecology (July, 1951-June, 1952). Edited by J. P. Greenhill, B.S., M.D., F.A.C.S., Professor of Gynecology, Cook County Graduate School of Medicine, Chicago. Cloth. $5.50. Pp. 575, with 98 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1952.

This valuable yearly review of obstetrics and gynecology is ably edited to present abstracts of publications of the past year considered most important in these fields. The result is an excellent review of the literature punctuated by cogent editorial comment.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specificially so stated.

QUERIES AND MINOR NOTES

WORK IN URANIUM MINES

To the Editor:—*A man has been working in a uranium mine for three and one-half months. He works nine hours daily in the mine, and the ore mined contains from 0.2 to 0.7% uranium. No attempt is made to determine the degree of contamination among the workers, who wear ordinary work clothes, but there is extreme radioactivity in the mine as determined by a Geiger counter. To date, this man has felt no ill effects. Is it dangerous for him to continue this work?* *M.D., Utah.*

Answer.—The radioactivity of most uranium ore is so low that damage from uranium would be more significant from the standpoint of chemical toxicity than from that of radioactivity. Absorption from the intestinal tract of uranium as present in ore is extremely slight. The chief hazard in a uranium mine, if the ore is in hard rock, is silicosis. So far as radioactivity is concerned, the significant hazard in a uranium mine again is not from the uranium itself but from the associated radon, which is usually present as a contaminant of the air. The risk related to radon varies with its concentration and with the amount of dust on which its decay products may be precipitated. The concentration varies from mine to mine. It may be controlled by ventilation. Long exposure to radon-contaminated air may be tolerated before there is evidence of harm. Most of the bronchial cancers encountered in the Schneeberg uranium miners did not develop until after 17 or more years of exposure to unfavorable conditions.,

UNEXPLAINED SWELLINGS

To the Editor:—*In a 17-year-old boy swelling of the right ear developed two years ago, persisted for eight months, and then slowly regressed. Six months later the opposite ear underwent a similar enlargement and regression. During this time the boy felt well. A year after the last episode of edema, the muscles of the right leg gradually enlarged until the circumference was about one-third greater than that of the left leg. There was no skin edema and no swelling at or below the ankle. The muscular strength, amplitude, and tendon reflexes were normal. There was no tenderness and no tumefaction. The muscles felt tenser than those in the other leg but otherwise showed nothing remarkable. The overlying skin was the same as that of the other leg. A careful exploration of the involved muscles by an orthopedic surgeon revealed nothing except questionable edema in the fascial planes. Results of several biopsies were reported normal by a competent pathologist. After the biopsy, the wound healed more slowly than would be expected; however, the initial enlargement gradually receded in three weeks. The boy is husky and has felt in excellent health. No difficulty was encountered with the enlarged leg except slight stiffness. Results of urine and blood tests were normal as was the erythrocyte sedimentation rate. The patient's history is normal, except for the usual infections of childhood, which were without notable complications. At no time has there been joint involvement or any indications of so-called collagen disease. What is your opinion?* *M.D., Washington.*

Answer.—This consultant once studied a case in certain respects similar to the one described. The patient complained of edema of the left lower forearm and back of the hand, which appeared in separate attacks over 24 hours as diffuse, somewhat indurated, nonerythematous, nonpruritic edema. It would occur from the midforearm to the fingers. On two occasions, the rapidity of onset necessitated the cutting off of a ring. After four or five hours, the edema was painful enough to require use of analgesics. The pain seemed to be related to overdistention of tissues, since the ends of the fingers became somewhat pale and cool during the attack. The radial pulse persisted. Once the edema formed, it took two to three weeks to subside completely. Prompt use of serial injections of epinephrine did not interrupt the onset or shorten the spells. The patient was admitted to the hospital for extensive laboratory studies. A thorough search for allergens, bacterial infection, and metabolic disorders was fruitless. The patient's attacks occurred with mental pressure. When the patient's job was changed, they ceased. The final impression was that they were some bizarre form of angioneurotic edema. No cause except a psychosomatic one could be found. The tendency for the same area of the body to be attacked repeatedly, as occurred in both patients, suggests that these two syndromes may belong to the same class of disorders.

VITREOUS HEMORRHAGE

To the Editor:—*What is the treatment for massive vitreous hemorrhage of unknown origin? In the absence of intraocular infection, would there be a possibility of posterior synechiae and would atropine be indicated immediately on the supposition that there might be infection? If so, for how long a period?* *M.D., Missouri.*

Answer.—There is no adequate medical treatment for massive vitreous hemorrhage of unknown origin. Evacuation of blood by cannula or scleral incision has been helpful in some cases, but is considered an extreme measure of last resort in cases of secondary glaucoma. In the absence of intraocular infection there is the possibility of posterior synechiae, but atropine is not indicated except in the presence of subnormal intraocular pressure. Instillation of miotics and gentle massage to prevent abnormally high intraocular pressure are indicated. In cases of recurrent intraocular hemorrhages, if intraocular pressure remains normal or low, dilatation of the pupil is desirable and atropine may be used indefinitely unless signs of intolerance or toxicity appear. Atropine will not be helpful if the pupil cannot be dilated.

ROUTINE TESTS FOR ALBUMINURIA

To the Editor:—*In the routine office determination of qualitative albuminuria, please compare the heating method with the nonheating chemical methods.*
Leonard Casser, M.D., Cresskill, N. J.

Answer.—The degree of sensitivity of the common qualitative tests for the detection of proteinuria is markedly dependent on the use of clear urine and on observation of the precipitated or heat coagulated protein against a black background. Most specimens must be cleared by filtration or centrifugation before testing. Under optimum conditions, all tests are sensitive enough to detect protein at the pathological level and to avoid positive indications of the small amounts normally excreted. For routine office use, heating methods are generally preferred. The heat and acetic acid or the Purdy heat test is preferred because either is slightly more sensitive than the cold tests and, in addition, because either can be made fool-proof against other substances, such as proteoses, mucin, Bence-Jones protein, resinous and emulsifying agents, and phosphates. It is recognized that the sulfosalicylic acid test is a good one under office conditions, especially when the mixture is warmed (not boiled) to detect proteoses. It is a bit less sensitive than the heat and acetic acid test. The need is not for greater sensitivity but for the recognition of conditions in the urine that may cause false positive reactions.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

TRICHLORETHYLENE (TRILENE) ANESTHESIA

To the Editor:—*Please give the indications for and contraindications to the use of trichlorethylene (Trilene) anesthesia in obstetrics. What toxic agent is produced by the mixture of trichlorethylene with soda lime, and what is its physiological effect on the body? How soon after trichlorethylene has been used may a different anesthetic be used through the soda lime?* Cloid D. Green, M.D., Canton, S. D.

Answer.—Trichlorethylene should be used for analgesia only. The mixture provided by the simple inhalers on the market usually consists of 0.65% trichlorethylene in air, not sufficient for deep anesthesia. Its use is contraindicated in patients who have respiratory difficulty or cardiac decompensation, because a high oxygen saturation is an important safeguard. The various analgesic agents, such as morphine and its derivatives, meperidine (Demerol), the barbiturates, and scopolamine do not interfere with the administration of trichlorethylene, but the concomitant use of epinephrine is contraindicated. Trichlorethylene should not be used in a closed anesthetic system. In the presence of soda lime and heat (125 C), trichlorethylene may be broken down into the poisonous gas phosgene (carbonyl chloride) and hydrochloric acid. Although the circumstances under which this change can occur are extremely rare, it should be guarded against. The early signs of drug toxicity are increased respiratory rate and irregularity of the pulse. If these signs occur during administration of trichlorethylene it should be discontinued. Any anesthetic agent can be used for the delivery following use of trichlorethylene; however, a short interval should elapse so it can be exhaled completely. Although the drug passes through the placental barrier readily, it does not increase the hazard of fetal anoxia, because of its rapid elimination.

PAIN AND SWELLING IN BOTH KNEES

To the Editor:—*A 14-year-old boy was hospitalized complaining of pain and swelling in both knees of four days' duration; he had no previous history of this nature, no history of previous respiratory infection, and no history of gonorrhea. Physical examination showed bilateral heat and effusion in both knees, which were tender to touch. Physical and electrocardiographic examination revealed no cardiac abnormalities except sinus tachycardia. The temperature ranged between 100 and 101.6 F for the first four days of salicylate therapy (8 to 10 gm. of sodium salicylate daily), then fell to normal. He improved subjectively, but the effusion and heat of both knees continued. His right knee was tapped, and 10 cc. of turbid straw-colored fluid was withdrawn. The laboratory reported "many pus cells" in the fluid, but no organisms were seen on smear or culture. Following this examination, he had a 13 day course of penicillin therapy; with omission of salicylates, low grade fever returned. There have been no changes in his cardiac status during this time, and no other joints have been affected. Is a purulent synovial effusion consistent with a diagnosis of acute rheumatic fever, or is another form of arthritis a more likely diagnosis?* M.D., Arizona

Answer.—A 14-year-old boy with fever and bilateral swelling of the knees has rheumatic fever until it is proved otherwise. This probability is increased by his temperature drop with salicylates and recurrence of fever during penicillin therapy. Turbid, straw-colored fluid is not necessarily purulent in character. The laboratory report of "many pus cells" also is very incomplete, as no quantitative count or differential count was made. It is therefore not possible from the laboratory report to know whether the effusion was truly purulent or not. A purulent effusion is not compatible with rheumatic fever. It is quite probable that the diagnosis is rheumatic fever and the joint fluid not purulent. Juvenile rheumatoid arthritis (Still's disease) must be considered in the diagnosis. If the boy recovers with salicylate and rheumatic fever treatment, however, the diagnosis of rheumatic fever is fairly well established. If the joint effusions are definitely purulent, then cultures should reveal the organism responsible. If cultures are positive, then sensitivity tests against various antibiotics should be made, as penicillin already has proved ineffective.

BURNING PAIN IN FOOT

To the Editor:—*A woman, 82 years of age, is in good health except for frequent burning pain in her right foot. The pain is always in the same spot in the instep, is severe, and is apt to be felt most when the patient's feet are warm. It is relieved somewhat by cooling of the foot. The skin temperature in this foot is definitely higher than that in the left foot. Arterial pulsations are unusually good for a woman of this age. Pernicious anemia has been ruled out, the gastric contents and blood picture being normal. One year ago the patient had bilateral swelling of both feet to such a degree that walking was difficult. The swelling did not extend above the ankles. There was no dyspnea or evidence of myocardial insufficiency. Foot roentgenograms were normal. The swelling subsided in two to three days with ammonium chloride therapy and elevation of the feet and has not recurred. The patient has been examined by the best peripheral vascular disease specialists in Detroit. Have you any suggestions as to diagnosis and treatment?*

M.D., Michigan.

Answer.—Burning pain in the feet relieved by cooling and elevation and aggravated by heat and dependency is due to erythromelalgia, which is a symptomatic, not an etiological, diagnosis. If polycythemia can be excluded, there remains a group of toxic, nutritional, and ischemic neuropathies that may be considered. A thorough neurological examination is desirable, since an irritative process in the sensory neurons anywhere from the thalamus to the sensory nerve endings may be present. The lesion may well be vascular, producing ischemia of the nervous system. Treatment is highly unsatisfactory. Repeated blocks of the posterior tibial nerve may be tried, but if this produces anesthesia without relief of the burning sensation, the origin of the lesion is higher and may even be due to spinal cord ischemia. Administration of large doses of acetylsalicylic acid or of vitamin B_{12} by injection or possibly even sensory nerve section at appropriate levels is necessary. If the burning pain is unrelieved by spinal anesthesia (a highly debatable procedure at the age of 82), thalamic pain sometimes may be alleviated by stellate ganglion block contralateral to the side of the lesion.

MYOCARDIAL INFARCTION

To the Editor:—*A 61-year-old man, previously in good health, had within six weeks four attacks of severe pains of a tearing, cutting, and burning character in both arms, which lasted for 15 minutes and stopped suddenly. These attacks were unrelated to effort, but, after a symptom-free interval of four weeks, pains on walking developed in the right arm, in the right shoulder region, and/or below the right scapula. The pains stop when the patient stops walking. He has tenderness in the right upper abdominal quadrant and rebound tenderness in the same area. X-ray examinations showed gallstones and osteoarthritic changes in the cervical spine. A resting electrocardiogram was normal, but an exercise test was followed by significant changes. The pains on walking can be prevented to some extent but not entirely by use of glyceryl trinitrate. Does this man have coronary disease or are the symptoms manifestations of cholecystitis and pericholecystitis, with secondary coronary insufficiency, indicating a need for surgical intervention, or is cervical osteoarthritis to be considered a cause?*

M.D., New York.

Answer.—The combination of effort pain relieved in part by use of glyceryl trinitrate and a "positive" exercise tolerance test indicate myocardial insufficiency. The description of intermittent tearing pain in both arms strongly suggests a dissecting aneurysm of the thoracic aorta; both this and the coronary artery disease may be manifestations of underlying, generalized atherosclerosis. Neither cholecystitis nor cervical osteoarthritis is unusual in this age group, and their presence is probably coincidental. It seems unlikely that they are the primary cause of this man's symptoms in the chest and arms. Cholecystitis may be responsible for the right upper abdominal quadrant and abdominal rebound tenderness.

AZOOSPERMIA

To the Editor:—*The reply to the query in* The Journal *July 18, 1953, page 1184, regarding the treatment of azoospermia is misleading. The particularly disturbing statement concerned the value of testicular biopsies and therapy based on such findings. It was said that "If the biopsies show temporary arrest due to pituitary insufficiency, injections of a potent pituitary product may be beneficial." I would like to offer four protesting points.*

1. It is impossible to diagnose a condition of "temporary arrest" of spermatogenesis on the basis of a testis biopsy alone. Conceding that there is a clinical entity of arrested spermatogenesis, the use of the term "temporary arrest" intimates a transitory state, or one that can be improved. Actually, azoospermia due to arrested spermatogenesis in the adult is a permanent condition. Cases cited in the literature of the successful hormone treatment of arrested spermatogenesis are so rare that one even doubts its attainment. For example, Simmons (Ann. New York Acad. Sc. *55:643, 1952) reports a case that was successful, but this man did not have spermatozoa in his semen either before or after the birth of his wife's two children. Apparently this author doubted the paternity by stating "Clinical patients cannot be as scientifically controlled as Carl Hartman's monkeys!"*

2. Again, how can one be certain that the arrested spermatogenesis is due solely to pituitary insufficiency? Factors are involved other than the pituitary function, and these cannot be evaluated solely by testis biopsies. Hormone and other studies must be made to try to arrive at the etiological basis, and even then it is not easy to determine the causative factor.

3. The term "potent pituitary product" is itself misleading. There are many pituitary-like and pituitary gonadotrophic substances available commercially, but in general these gonadotrophic substances are not purified extracts nor are they efficacious. Only recently has a truly "potent" anterior pituitary gonadotrophic substance been isolated in pure form that is highly potent; however, this product is not yet available on the commercial market.

4. Finally, it should be pointed out that injections for azoospermia, whether they be from the pituitary, testis, or other source, have hardly ever resulted in offspring. Injection therapy for azoospermia has been overdone; and injection therapy for azoospermia with present-day products must be reduced to a minimum if used at all. For example, at the recent World Congress on Fertility and Sterility in New York City in May, 1953, it was generally agreed that aside from surgical therapy in cases of a blocked vasa deferens and preventive therapy in young men, injection therapy with hormones of any type had not proved to be of any value in complete azoospermia.

VACCINATION OF CHILD WITH ECZEMA

To the Editor:—*I would like to comment on the answer in* The Journal, *Aug. 1, 1953, page 1392, to the question of whether a child with atopic dermatitis should be vaccinated against smallpox. Your consultant states that it is not necessary to withhold smallpox vaccination in such cases. I believe that most dermatologists agree that the risk of eczema vaccinatum as a direct consequence of such vaccination far outweighs the protection afforded against the almost extinct disease smallpox. I am informed by the Los Angeles Health Department that only 16 cases of smallpox were reported in the United States in the first half of 1953. The physician should bear in mind that far from being a benign disease, eczema vaccinatum is nearly always serious and occasionally fatal. Also the absence of any specific agent such as an antibiotic for the treatment of infections caused by vaccinia virus renders the management of this disease especially difficult. The answer given is further confused by the statement that "A kaposiform eruption of the varicelloid or herpetic type may develop." This is obviously in error, since this latter disease is caused by the herpes simplex virus and bears no etiological relationship to eczema vaccinatum. In view of the heavy risk involved with only a relatively small gain in prospect, the vaccination of a child with atopic dermatitis would seem to be a risky and unreasonable procedure.*

To the Editor:—*In* The Journal, *Aug. 1, 1953, page 1392, is an answer regarding smallpox vaccination of a child with eczema. This should be a case particularly suitable for the skeptophylactic method of vaccination described by me in the* Annals of Allergy *(9:85-88 [January-February] 1951), which is so-called because of the rapid evolution of the second or intradermal injection, resulting in an immune reaction rather than a primary take. Advantage is taken of the difference in incubation periods between infection in the skin and in subcutaneous tissues. The virus is injected first subcutaneously; then a week later before inflammation begins, a second injection is given intradermally. The second injection causes a papule within 24 hours, and neither becomes painful in children if Cutter's vaccine is used. There is no material to be transferred to another site. One capillary tube of virus is mixed with 1 ml. of saline solution, and 0.05 ml. is given at each injection.*

TREATMENT OF RECTAL PROLAPSE

To the Editor:—*I would like to comment on the answer on the treatment of rectal prolapse in Queries and Minor Notes, April 18, 1953. The following statement was made: "Rectal prolapse in infants and children is mucosal in almost every instance." This has not been our observation in this section of India. The greater number of patients that we see here have a true prolapse involving all the layers of the bowel. In severe and in long standing cases in which there are changes in the bowel wall that may amount to ulceration—such cases are seen frequently in children of poor village families—we have had very good results from amputation of the prolapse, in the manner of Mikulicz, with anastomosis of the cut edges of the bowel, which then is replaced within the anus. A purse string suture of silk is placed at the anal orifice and tied loosely around a finger. This prevents the infant from straining to pass the area of anastomosis and thus cause a recurrence of the prolapse. This suture is maintained for one to two weeks, during which time the stools are kept soft. Infants stand this procedure very well, and the amount of shock is minimal. In mild and in early cases, replacement of the bowel with strapping of the buttocks has been our treatment of choice.*

SOFTENED WATER

To the Editor:—*In Queries and Minor Notes in* The Journal, *Aug. 8, 1953, page 1498, I note a question on softened water. The process of water softening is replacing the magnesium and calcium with sodium. Hence the water has a high sodium content. That is why patients suffering from vertigo or dropsy often improve after combining distilled water with their medication.*

PROLONGED LABOR

CLINICAL EVALUATION

John R. McCain, M.D., Atlanta, Ga., Clarence L. Anderson, M.D., Lakeland, Fla.
William M. Lester, M.D., Atlanta, Ga.
and
Joseph W. Pilkington, M.D., St. Petersburg, Fla.

The proper management of a long labor is one of the most difficult problems in obstetric practice. Long labor should be prevented if possible, but if prolonged labor does develop the physician should know how to provide the maximum safety for the mother and for the infant. He should be aware of the indications for, and the dangers of, operative intervention.

The purpose of this study is to evaluate clinically 158 cases of prolonged labor that occurred at Grady Memorial Hospital. The conditions found to be significant in these labors are discussed in their relationship to (1) the etiology, (2) the course of labor, (3) the indications for treatment, (4) the results for the infant, and (5) the type of labor to be expected if a later pregnancy occurs. For the cases reported here, the onset of labor is defined as the time at which the uterine contractions become painful and continue to produce dilatation and effacement of the cervix. The labor is considered as prolonged if the total elapsed time from the onset of labor until the delivery of the infant is 30 hours or longer and the infant weighs 1,500 gm. or more.

The 158 patients whose labors are evaluated in this paper were among a total of 19,159 women delivered under the supervision of the department of obstetrics and gynecology of Emory University at Grady Memorial Hospital between July 1, 1948, and Dec. 31, 1951. The incidence of prolonged labor was 0.8%. No maternal deaths occurred among the patients with prolonged labors during the years of this report. Stillbirths or neonatal deaths occurred in 33 infants of the 158 pregnancies, an infant mortality rate of 20.9%. The low incidence of prolonged labors and the high infant mortality rate reported here as compared with other studies[1] suggest that the onset of labor must have been timed rather strictly at Grady Memorial Hospital.

As a background for the interpretation of the results in this paper, the following information is given regarding the obstetric service at Grady Memorial Hospital. All of the patients are service cases and are delivered by the hospital house staff under the supervision of the members of the visiting staff of the department. The stillbirth rate for the service is 1.67%. The neonatal death rate is estimated at 2%; it cannot be determined accurately since it is necessary to discharge many patients very early in the puerperium because of a lack of bed space. The incidence of premature deliveries is 12%. The incidence of cesarean section during the years of this report was 0.72%.

ETIOLOGY AND INCIDENCE

Uterine inertia was the major cause for the prolonged labors in this study. Investigations have been made by other authors concerning the abnormal variations in uterine contractions and their significance in the etiology of prolonged labor.[2] The information in this report regarding the etiology of prolonged labor is limited to that which could be obtained from the clinical observation of the patients. Inertia was encountered in all except three, and in these the long labor was due to fetopelvic disproportion. Primary uterine inertia was encountered in 145 of the 158 patients. In 77% of all the cases, it occurred alone, without other complications such as disproportion. Because of the high incidence, it is evident that this paper is, in effect, a clinical evaluation of primary uterine inertia as a cause of prolonged labor. (The uterine inertia was secondary to oversedation or exhaustion in six patients, and in four it was secondary to fetopelvic disproportion.)

From the Department of Obstetrics and Gynecology, Emory University School of Medicine, and Grady Memorial Hospital.

Read before the Section on Obstetrics and Gynecology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

Hoeber, Inc., 1949, chap. 5.

The presence of a disproportion between the infant and the maternal pelvis was determined from a review of the clinical opinions during labor, the presentations and positions of the infants, roentgenologic pelvimetry studies, and the actual weights of the babies after delivery. As determined by these conditions, fetopelvic disproportion was observed in 31 patients, but in almost all cases the degree of the disproportion was borderline. The roentgenologic pelvimetry studies, in general, confirmed the clinical impressions regarding the pelvic capacity and the size of the fetus. Uterine inertia was present in all except three of the cases of disproportion. The poor uterine contractions made it difficult to appraise the extent to which the disproportion itself contributed to the prolonged labor. The inertia made it almost impossible to obtain a satisfactory "trial labor" in most of the patients with borderline disproportion. The complications in the labors of patients with disproportion caused the death of 12 babies, an infant mortality rate of 38.7%, as compared with a 16.5% infant loss among the patients without disproportion.

The incidence of the types of presentations and positions of the infant varied from those encountered in normal labors. For cephalic presentations the position that persisted throughout most of the labor was occiput anterior in only 33 patients (20.9%), occiput transverse in 51 patients (32.3%), occiput posterior in 57 patients (36.1%), and persistent occiput posterior in 4 patients (2.5%). The presentation of one infant was a transverse lie. Breech presentations occurred in 12 of the patients, an incidence of 7.6%. The breech deliveries were the only ones in which a definite relationship could be established between the presentation or position of the fetus and the prognosis for the infant. Of the 12 breech presentations, six babies did not survive.

The weight of the infants affected their survival. Half of the 14 babies that weighed 4,000 gm. or more did not live, even though some of them did not show any evidence of a fetopelvic disproportion. The infant mortality rate was approximately the same (33%) for the 6 premature infants and for the 22 infants with weights ranging from 3,650 to 4,000 gm. The mortality rate was the lowest (14.7%) for the 116 infants weighing from 2,500 to 3,650 gm.

The age of the mother influenced the prognosis for the infant. The 71 patients under 20 years of age lost seven babies. On the other hand, the 25 patients over 30 years of age lost 12 infants.

A study of the parity of the patients in this series showed that 85.4% were primiparas. The infant mortality rate was twice as great for multiparas as it was for the primiparas. The 135 primiparas lost 24 infants (17.8%), and the 23 multiparas lost 9 infants (39.1%). The labors of the multiparas were complicated by a high incidence of fetopelvic disproportion (11 cases), breech presentations (5 cases), and large infants (eight weighing 4,000 gm. or more). An interval of more than 15 years had elapsed since the last previous delivery for four of the multiparas. Incidentally, the 23 multiparas had delivered a total of 65 premature or term infants before the prolonged labor of this report. Ten of the 65 infants were premature, and 7 of these had died. Seven of the 55 term infants did not live. Although complete records of all of the 65 previous deliveries are not available, no case of fetopelvic disproportion was found. A prolonged labor occurred with an earlier pregnancy in five of the multiparas, but the infants of those labors lived.

Rupture of the amniotic membrane before the onset of labor occurred in 18 of the 158 prolonged labors, and in 17 of these the rupture was spontaneous. The incidence of the premature rupture of the membranes was about normal, but the infant mortality was unusually high since nine of the babies were lost. Although the artificial rupture of the membranes was used to induce labor in approximately 150 women during the years of this study, a prolonged labor occurred in only one of the patients. (At Grady Memorial Hospital labors are rarely induced by the artificial rupture of the membranes except for a toxemia of pregnancy.)

ARREST OF PROGRESS IN LABOR

Progress during the course of labor was determined by the descent of the presenting part of the infant into the pelvis or by the dilatation or effacement of the cervix. Progress was considered to be arrested if, during a period of several hours, no significant change occurred in the descent, dilatation, or effacement. The slowing of progress in labor as a result of therapeutic sedation was not considered as an arrest. In the 158 patients in this group, progress was arrested in 153 of the labors. The arrest occurred before the end of 24 hours of labor in 118 of the patients. Only 16 women continued in labor over 30 hours before progress stopped. The arrest was primarily a problem of the first stage of labor. The labor of 100 patients became arrested while the cervix was dilated 4 cm. or less. At the time of the arrest, the cervix was dilated more than 6 cm. in only 20 cases.

Progress usually became arrested with a cervical dilatation of 4 cm. or less and after approximately 18 to 24 hours of labor. The attending physician should seriously consider the use of sedation or stimulation if these conditions begin to develop in the course of labor. The proper use of sedation and stimulation might maintain normal progress in labor and prevent many of the later complications. From the information in this study, however, it was impossible to predict the final length of the labor or the result for the infant from the variations in the time and in the cervical dilatation when the progress stopped.

The prognosis for the infant at the time of the arrest of progress could be predicted from the station of the presenting part of the infant and from the status of the amniotic membrane, whether intact or ruptured. The infant mortality rate was 15.4% if the presenting part of the infant had become engaged by the time progress became arrested, but it was approximately twice as great (28.8%) if engagement had not occurred. It can be seen from table 1 that the condition of the amniotic sac at the time of the arrest was considerably more important than the station of the presenting part. If the membranes had already ruptured at the time of the arrest, the infant mortality rate was 38.3%, or four times as great as when the membranes were intact at that time. The prognosis for the infant at the time of the arrest was much better if the membranes were intact, even with the presenting part unengaged, than it was if the membranes were ruptured even though the presenting part had already become engaged. The combination of the two conditions gave a better indication of the danger for the infant. The prognosis was poorest if the arrest took place after the membranes had ruptured but the presenting part was still unengaged. Over half of the infants (54.2%) were lost. The infant mortality rate in these patients was seven times as great as it was among those in whom the membranes were still intact and the presenting part of the infant was engaged at the time of the arrest.

TREATMENT TO IMPROVE PROGRESS IN LABOR

The three methods usually suggested to improve the rate of progress in labor are: rest or sedation, artificial rupture of the amniotic membrane, and pituitary extract. It is not the purpose of this paper to outline a specific plan of treatment for patients with prolonged labor. The treatment given to the patients in this study is reviewed to the extent that it appeared to affect the duration and the result of their labors.

Table 1.—*Prognosis for the Infant at the Time of Arrest of Progress in Labor**

	Condition of Amniotic Membrane at Time of Arrest								
	Ruptured			Intact			Totals		
Station of Presenting Part at Time of Arrest	No. of Cases	Infants Died	% Infants Died	No. of Cases	Infants Died	% Infants Died	No. of Cases	Infants Died	% Infants Died
Unengaged	24	13	54.2	35	4	11.4	59	17	28.8
Engaged	36	10	27.8	55	4	7.3	91	14	15.4
Total	60	23	38.3	90	8	8.9	150	31	20.7

* Of the 158 cases of this report, arrest did not occur in the labors of 5 patients, and information concerning 3 others could not be secured; 2 infants were lost in the 8 cases not included.

Table 2.—*Effect of Artificial Rupture of Amniotic MembraneAfter the Arrest of Progress in Labor*

	Membranes Not Ruptured Artificially			Membranes Ruptured Artificially			Totals		
Station of Presenting Part	*No. of Cases*	*Infants Died*	*% Infants Died*	*No. of Cases*	*Infants Died*	*% Infants Died*	*No. of Cases*	*Infants Died*	*% Infants Died*
Unengaged	22	3	13.6	13	1	7.7	35	4	11.4
Engaged	32	4	12.5	23	0	0	55	4	7.3
Total	54	7	13.0	36	1	2.8	90	8	8.9

Morphine combined with barbiturates was used for the therapeutic sedation of the patients of this report, but it was not possible to demonstrate that the sedation consistently affected the course of labor either favorably or unfavorably. After therapeutic sedation, an occasional patient had a definite improvement in the rate of progress and delivered quickly. Generally, however, progress seemed to be improved very little after the use of sedation. Although no definite benefit could be attributed to the therapeutic sedation, we believe that it proved valuable in maintaining the general condition of the patients and thereby preventing exhaustion. Sedation for the purpose of the relief of pain in labor (for analgesia and amnesia) interferred with the normal progress of labor in four cases by producing a secondary uterine inertia.

The most effective therapy found in this study for improving the progress of labor after it had become arrested was the artificial rupture of the amniotic membrane. In 90 patients, the progress was arrested while the membranes were still intact, and eight babies were lost. The effectiveness of the artificial rupture of the membranes can be seen in table 2. If the membranes were not ruptured artificially, the infant mortality rate was 13%, and it was approximately the same whether or not engagement had occurred before the arrest of progress. If the membranes were ruptured artificially after the arrest had occurred, the infant mortality rate was 2.8%. No prolapsed umbilical cords occurred from the rupture of the membranes, whether the rupture was spontaneous or artificial.

The prognosis for the patient's labor after an arrest could be predicted by the response to treatment combining the rupture of the membranes with the use of pituitary extract (unless a contraindication for pituitary extract was present). If the progress in labor was satisfactory after these means of treatment were instituted, a successful vaginal delivery could be predicted. If the progress was not satisfactory, the likelihood of a successful vaginal delivery was slight. In a prolonged labor it is often quite difficult to determine whether the amount of progress within a given period of time should be considered as a satisfactory response. The decision is made more difficult by the uterine inertia that is usually present. Treatment consisting of the use of pituitary extract (unless contraindicated) after the rupture of the membranes should be continued only as long as a successful vaginal delivery can be expected. A vaginal delivery should be considered successful if the cervix dilates completely and if a normal child is delivered without injury to the mother. It should be considered unsuccessful if the patient is delivered by cesarean section, vaginally before complete dilatation of the cervix, or vaginally of an infant that does not survive.

From table 3 it can be seen that a successful vaginal delivery occurred in 114 patients. If the patients had not delivered within eight hours after the rupture of the membranes and the use of pituitary extract (unless contraindicated), a successful vaginal delivery occurred in only half of the 59 cases. Under these circumstances, serious consideration should be given to cesarean section at the end of eight hours of treatment unless vaginal delivery is imminent. If cesarean section had been employed for all of the cases of this report in which the delivery was not imminent within eight hours after the treatment was begun, many disastrous operative procedures would have been avoided. The incidence of cesarean section for the 158 prolonged labors would have been 35%. If all of the infants from the additional cesarean sections had survived, the infant mortality rate for the study would have been 8%. Of course, as indicated by 14 cases in this report, it may become evident before the end of the eight hours of treatment that a successful vaginal delivery will not occur. In such patients, if cesarean section in indicated, it should not be delayed until the end of eight hours of treatment.

TABLE 3.—*Interval Between Treatment of Arrest in Labor by Pituitary Extract and/or Rupture of the Membranes and Delivery*

	Delivered Within 8 Hr. After Treatment Begun	Delivered Over 8 Hr. After Treatment Begun	Total
Successful vaginal delivery.........	85	29	114
Unsuccessful vaginal delivery.......	14	30	44
Total..........................	99	59	158

RESULTS FOR THE INFANT

The methods used for delivering the infants of this report are summarized in table 4. The length of the labor affected the results for the infant. The infant mortality rate for the 115 patients whose labor lasted less than 48 hours was 13.9% (16 deaths). For the 19 women whose labor lasted from 48 to 60 hours, the infant mortality rate was 21.1% (4 deaths), and for the 24 women whose labor lasted 60 hours or longer the infant mortality was 54.2% (13 deaths).

The underlying causes of death for the infants in this study were predominantly intrapartum fever and operative procedures for delivery. The 43 cases of labors lasting over 48 hours included 21 patients whose labors were afebrile. These 21 women lost five infants, but three of the five were delivered by difficult operative procedures. Labors lasting over 48 hours, without fever and without operative deliveries, ended with the death of only two infants, and both of these were premature babies.

It is logical to expect intrapartum fever to increase the danger to the infant because of the increased oxygen requirements from the temperature elevation.[3] If the fever in labor is of long duration, the requirement of more oxygen for the fetus could easily become critical and could cause a greater number of infant disasters. Fever of 1 degree (F) or more developed during the labors of 52 patients. The fever began during the first 12 hours of labor in 14 of the women, and seven of the babies were lost. The 36 women with fever less than 36 hours before delivery lost six infants. By contrast, the 16 patients who had had fever over 36 hours before delivery lost 13 babies (81.2%).

Operative deliveries, as shown in table 4, were associated with a higher infant mortality rate than spontaneous deliveries. It is true, however, that 8 of the 22 infants that did not survive after operative delivery died in labor before the operation was begun. If these eight infants are combined with the infants delivered spontaneously, it is found that the 109 patients lost 19 infants (17.4%) without operative interference. An operative delivery was begun in 49 patients while the infant was still living, and 14 babies (28.6%) did not survive.

The evaluation of the operative procedures listed in table 4 reveals that the incidence of cesarean section was 7.6% for the 158 prolonged labors. Fetopelvic disproportion was a contributing factor in the indications for cesarean section in 10 of 12 patients. Although 121 women in this study had a prolonged labor associated with primary uterine inertia, without evidence of fetopelvic disproportion, only 2 of them were delivered by cesarean section. These two cesarean sections were not performed until after more than 80 hours of labor; both infants died. (The teaching of this department and of this hospital is that primary uterine inertia can be an indication for cesarean section. The information in this report demonstrates that such a policy is not carried out in practice.) The failure to perform cesarean sections for primary uterine inertia among the cases of prolonged labor in this report provides the opportunity of studying the results to be expected if all cases of primary uterine inertia are delivered vaginally.

TABLE 4.—*Method of Delivery of Infants*

	Spontaneous	Assisted Breech	Breech Extraction	Low Forceps	Midforceps, Anterior Position	Midforceps Rotation	Duhrssen's Incisions	Craniotomy	Cesarean Section	Total
Survived	90	5	1	7	5	6	2	0	9	125
Neonatal death.............	5	0	1	1*	0	3*	3	0	1	14
Stillborn	6†	2*	1	0	0	3	1	4‡	2	19
Total..................	101	7	8	8	5	12	6	4	12	158

* Three infant deaths occurred after gross errors in operative technique at deliveries.
† Tight loop of umbilical cord about the neck of two infants.
‡ One infant was hydrocephalic, a frank breech presentation. (One of the 12 breech presentations was delivered by cesarean section.)

The significance of intrapartum fever and of operative deliveries as causes of infant mortality becomes more impressive if they are considered together. Fever during labor was present before the death of the infant in 19 cases. Fourteen infants died when operative deliveries were started while the baby was still alive. Only five infants died that had not been delivered after febrile labors or by operative procedures. One of these five labors was in a mother with eclampsia, one labor ended in the rupture of the uterus, and one of the five infants had a tight loop of umbilical cord around its neck.

COMPLICATIONS IN LABOR

Unusual complications developed in the labor of 14 patients. Tetany of the uterus was observed during the labor of 10 women, and seven of the infants died. The umbilical cord prolapsed while delivery was being attempted in two patients, and both infants were lost. Rupture of the uterus occurred in one case. It took place almost immediately after an intravenous clysis containing pituitary extract was begun to stimulate the labor of a multipara who was considered to have an adequate pelvis. A pathological retraction ring (Bandl's ring) developed in the labor of a patient with a hydrocephalic infant. The infant was a breech presentation, and the hydrocephalus was not recognized until the delivery began. The roentgenologic studies during labor had not demonstrated any deformity of the fetal head.

---

[3] Best, C. H., and Taylor, N. B.: The Physiological Basis of Medical Practice, ed. 5, Baltimore, Williams and Williams Company, 1950, p. 621.

POSTPARTUM COURSE

Postpartum infections developed in 23 patients (14.6%). Endometritis was responsible for infection in 16 patients, parametritis in 2, pyelonephritis in 4, and bronchopneumonia in 1. Almost without exception, the morbidity in these patients was of short duration. Postpartum hemorrhage and shock were not a problem.

LATER PREGNANCIES

The subsequent pregnancies of the patients in this report were reviewed. By April 1, 1953, 77 of the 158 women had delivered a total of 101 premature or term infants after their experience of prolonged labor. The later pregnancies were strikingly normal in their duration and in the results for the infants. Only 16 of the 101 later labors lasted over 12 hours, and only 2 of these lasted over 24 hours. A prolonged labor occurred in only one later pregnancy. This labor lasted 31 hours, and it was terminated at that time by cesarean section. In the later pregnancies, three premature and two term infants died. Two of the five infants died before the onset of labor, and two premature infants, delivered after less than 12 hours of labor, died in the first day of life. One baby died after hemorrhage and shock developed during the labor of a patient with a placenta previa.

All except 12 of the later pregnancies were delivered spontaneously. Six women who had been delivered by a cesarean section at the prolonged labor of this report had eight later pregnancies again delivered by cesarean section. Two patients were delivered for the first time by cesarean section in a later pregnancy. The infant that died in the labor complicated by the placenta previa was delivered as an assisted breech. One 1,325 gm. infant, which died before the onset of labor, was delivered from a transverse lie by a version and extraction.

The later pregnancies of the women who had had primary uterine inertia in their prolonged labor were delivered after short labors, with the uterine contractions of normal character. Of 31 patients with fetopelvic disproportion complicating the prolonged labor, 13 had 17 later deliveries. Ten of the 17 later pregnancies were delivered by cesarean section.

SUMMARY

The 158 prolonged labors occurring among 19,159 deliveries are evaluated clinically. All of the mothers lived, but 33 of the infants died. Primary uterine inertia was present in the labor of 145 patients. It was the only etiological factor recognized clinically in 121 of the cases. Fetopelvic disproportion was found in 31 women, and 12 of the babies were lost (38.7%). The babies were delivered as breech presentations in 12 cases, and half of the infants died. Of the infants weighing 4,000 gm. or more, 50% did not survive. The age of the patient and her parity significantly affected the labor and its results. Patients over 30 years of age lost 50% of their babies. The patients were primiparas in 85% of the prolonged labors. Fetopelvic disproportion and/or presentations of the infant other than cephalic occurred in 65% of the multiparas.

Progress became arrested in 75% of the cases before labor had lasted 24 hours. The cervix was dilated not more than 4 cm. in 100 patients at the time that the arrest of progress occurred. If progress became arrested, with the membranes ruptured and the presenting part still unengaged, over 50% of the infants did not survive. The most effective treatment after the arrest of progress in patients with the amniotic membrane still intact was artificial rupture of the membranes. If the patients did not deliver within eight hours after the rupture of the membranes and the use of pituitary extract (unless contraindicated), the results obtained by vaginal deliveries were found to be unsuccessful in half of the cases. The 43 patients in labor over 48 hours lost 40% of their babies. The underlying causes of death for the infants were predominantly intrapartum fever or operative delivery. The patients who had had fever for more than 36 hours before delivery lost 81.2% of the infants. Elevated temperatures during labor or operative procedures at delivery occurred in all except two of the cases in which the infant died after 48 hours of labor.

The later pregnancies of the women whose prolonged labor had been caused by uterine inertia alone were delivered spontaneously, after short labors, with excellent results for the infant. In the patients with prolonged labor complicated by fetopelvic disproportion, over 50% of later infants were delivered by cesarean section.

Tuberculosis.—Although we have thus artificially removed tuberculosis from our consciousness by removing its victim from our daily experience, the never-to-be-forgotten fact is that there are today some 35,000 to 40,000 persons with active tuberculosis in New York City alone, 400,000 in the United States, not to speak of the 50,000,000 tuberculous persons in the rest of the world. More than half of the adult population of our city reacts positively to tuberculin, a fact which proves that most of us are infected by contact with tuberculous persons in the course of our normal lives, and become, from then on, carriers of living, virulent bacilli. It is becoming evident that the morbidity rate is not falling as fast as the mortality rate. In New York City, for example, there were 17,645 known cases of pulmonary tuberculosis in 1931; the number was still 17,499 in 1952, 20 years later. And these figures do not tell the whole story, for it is well known that a large percentage of tuberculous patients (probably close to 50%) are never entered in official records and continue to forge unsuspected the chain of infection among their fellow men. In other words, we have been more successful in retarding death from tuberculosis than in protecting against infection or in curing the disease.—Rene J. Dubos, Biologic and Epidemiologic Aspects of Tuberculosis, *The American Review of Tuberculosis,* July, 1953.

CLINICAL OBSERVATIONS AND INTERPRETATIONS OF ABNORMAL AIR SPACES IN THE LUNGS

A NEW CONCEPT OF THEIR ORIGIN

Edgar Mayer, M.D., and Israel Rappaport, M.D., New York

Abnormal air spaces in the lung parenchyma, such as cysts, bullae, and pneumatoceles, have been the subject of an increasing amount of discussion during the past 25 years. Large-scale roentgenographic surveys have revealed many such cases in which the lesions were clinically latent. Long-range observations have revealed their variable clinical evolution, and increasing numbers of surgical explorations have yielded data on their morphological features. All of this has thrown much new light on these remarkable pulmonary changes.

In view of all the accrued information there is now renewed discussion of cystic, bronchiectatic, and bullous lung changes. In recent literature there is increasing cognizance of the fact that these changes are related to each other and, in some manner, to emphysema, the essential basis of which is air space abnormality. Brief reading of current writings should convince us that there is now an urgent need for a better understanding of the pulmonary conditions associated with abnormal air space formation, since their incidence appears to be increasing and since we are beginning to make new approaches in treatment.

In a recent publication we have outlined a new concept of the common origin of cystic, bronchiectatic and emphysematous lung changes.[1] We will here discuss clinical observations and present the broader aspects of our concept by which all these phenomena can be reduced to the common denominator of air space disorder as a manifestation of abnormal lung function resulting either from developmental or from pathological changes in the lungs.

Some of the more important data regarding abnormal air spaces in the lungs gleaned from recent literature and borne out by our own observations are significant: 1. They are frequent clinical findings and their incidence appears to be increasing. 2. They are often present in a clinically silent state in otherwise healthy persons, revealed mostly as accidental roentgenographic findings. 3. Often they reveal themselves first by spontaneous pneumothorax, by sudden hemoptysis, by intercurrent infection, or by so-called pseudoasthma. 4. They are found at all ages and increase in frequency from childhood to advancing age. 5. In infants and children their incidence is already far beyond that conceivable for congenital anomalies. 6. They are often considered congenital, although clinical observation most frequently indicates acquired origin. This is so because there are often morphological features that to many pathologists suggest developmental rather than pathological origin. Against this origin, however, is the fact that such changes are exceedingly rare in the newborn and stillborn.

The various lung changes under discussion here are so often found combined that great confusion in nomenclature has resulted in such descriptive terms as cysts, bullae, pneumatoceles, cystic bronchiectasis, cystic emphysema, bullous emphysema, pneumocysts, vanishing lungs, and honeycomb lungs. This indicates, however, their close relationship to one another and to emphysema.

Development of air space disorders has been observed at all ages in patients whose lungs previously appeared normal. In infants and children particularly it is not uncommon to see such lung changes appear and disappear, enlarge in size, or alter in number over prolonged periods of observation. Dilatations of bronchi, for example, bullae, and their combinations may appear and then disappear in infants a few days or weeks old, or they may be followed by the formation of permanent cysts, pneumatoceles, or cystic bronchiectases. In some cases cystic or bullous structures increase in size merely by hyperinflation, due to mechanical obstruction of abnormal air spaces, with compression and displacement of the surrounding lung. In other instances, these structures seem to have increased by atrophy of lung structures, resulting in truly "vanished" lungs. In hyperinflated air spaces reversibility is frequently observed. Complete reversibility has been accepted as the criterion of pneumatoceles, but considerable extent of reversibility is common also in other air space disorders with fluctuations in the degree of hyperinflation and in the degree of patency of bronchial obstruction.

Operation of check valve obstruction has been demonstrated for cysts and bullae as well as for pneumatoceles. This has led to such confusion that distinction between them in practice has become virtually impossible, although it is often insisted on in theory. It becomes clear that this theory is no longer feasible, from the fact that even morphological differentiation is nearly impossible.[2]

In bronchiectatic conditions, there may be cystic distention of structures in some areas, while in others saccular and cylindric changes prevail. Also, at times cystic structures have been seen to shrink subsequently into sacculated and cylindric bronchiectases. It has been increasingly shown that cystic and bronchiectatic changes in the lungs, described as honeycomb lungs, may be associated with and perhaps produced by metabolic disorders. These include xanthomatosis, biliary cirrhosis, tuberous sclerosis, diabetes insipidus, pancreatic and pituitary insufficiency, lipoid granulomatosis, scleroderma, and reticuloendotheliosis. Recent experience has also shown that in diffuse extensive granulomatosis and fibrosis of the lungs, bullous changes resembling cysts

are produced almost regularly if the process is severe enough. These include berylliosis, sarcoidosis, and atypical granulomatosis and fibrosis of the lungs. Furthermore, massive emphysema often develops acutely with abrupt production of bullae and cyst-like pulmonary changes in infants and young children afflicted with diffuse acute bronchopneumonias, especially of staphylococcic origin.

From clinical observations, borne out by recent literature, it is our impression that a shift from acute suppurative bronchiectatic to more chronic cystic and bullous changes is now taking place. With the advent of the antibiotic era a marked decrease has occurred in the incidence of bronchopulmonary suppurative processes associated with bronchiectatic changes, while that of cystic and bullous changes has increased. Suppurative bronchopulmonary processes treated with antibiotics are now frequently brought under control, leaving cystic residues indistinguishable from identical changes in cases without evidence or history of preceding inflammatory process. Also the clinicopathological picture of cystic residues of inflammatory processes and that of cysts complicated by infection are today more difficult to separate from one another.

CURRENT CONCEPTS AND PROBLEMS

The long list of confusing classifications of pulmonary air space abnormalities clearly shows that all efforts to bring order into their clinical and pathological interpretation have so far failed. The trend is to separate them into two groups: the developmental and the pathological. In the first group are classified localized abnormal air spaces characterized by morphological features that are interpreted by many pathologists as indicative of developmental origin; in the second group are classified localized or diffuse abnormalities the clinical appearance of which is much like that of emphysema. These are therefore identified with the latter and are looked on as manifestations or forms of it. The implications arising from these classifications have brought forth added problems.

Problem of Acquired Origin of Developmental Abnormalities.—Abnormal air spaces showing morphological features of a developmental nature have been generally accepted as indicative of congenital origin. At the same time, however, clinical observations have established that all but an insignificant few are of acquired origin. With this conflict there arose the problem of reconciling the features of developmental nature with those of acquired origin. In a recent publication [1] we discussed a concept that seemed a reasonable answer. We postulated that abnormal air spaces may develop on the basis of developmental defects that have arisen during the postnatal period of growth of the lungs, when metabolic disturbances have interfered with their normal postnatal development. In clinically manifest severe insufficiencies of pancreatic, hepatic, and pituitary origin, the metabolic disturbances are commonly associated with cystic and bronchiectatic lung changes. It is logical to assume that metabolic disturbances of lesser degrees interfering to a lesser extent with postnatal lung development may yet leave developmental defects in the lungs in latent form.

Substantial support in favor of this was found by Medlar [4] in recent pathological studies. He interprets his findings as indicating that developmental defects account for the origin of all bronchiectatic and some cystic changes in the lungs. Clinical observations have established the fact that bronchiectatic, cystic, and emphysematous lung changes are practically inseparable. We believe therefore that latent developmental defects may evolve later into abnormal air spaces, manifesting themselves in cystic and bullous changes. When such changes are present in localized form, it is a reasonable assumption that they could have originated in localized developmental defects. In lung areas so affected normal lung function has obviously failed to develop from the start. How this may be linked up with the broad concept of air space formation as the normal visceral lung function that begins at birth will be discussed later. At this point it should be noted that there is suggestive evidence that developmental defects imply a disturbance in the autonomic regulation of the visceral lung function.[5] In this sense then, the abnormal air spaces to which they subsequently give rise may be interpreted as manifestations of disturbed visceral lung function restricted to localized areas. Since this function does not begin until birth, obviously abnormal air spaces can be acquired only after that.

Problem of the Primary Factor in Localized Air Space Abnormalities.—The prevailing opinion is that localized abnormal air spaces are produced by an obstructive check valve mechanism and that their clinical behavior bears this out. We believe, however, that these observations merely indicate that check valve obstruction plays an important role in the clinical evolution of localized cystic and bullous changes. Certainly when lung changes show developmental features, obstructive hyperinflation is only a secondary factor accounting for the progressive increase of an already preexisting abnormal air space.

Clinical observations indicate that no distinction is possible between lung changes with or without developmental changes. In abnormal air spaces produced by pathological processes, it is a reasonable assumption that such changes at the site play the primary role. It may also be assumed that in all abnormal air spaces where check valve obstruction hyperinflates, this is preceded by such an abnormality. We believe that check valve obstruction brings about excessive hyperinflation only in the presence of abnormal air spaces at the site affected, and that check valve obstruction is not the only factor in the mechanical overdistention of abnormal air spaces. The operation of still another mechanism, is to be discussed later.

The pathological findings of Medlar not only have confirmed our concept but have also shown that developmental defects are so localized and restricted in extent that they remain clinically latent, invisible, and undemonstrable by clinical examination. When mechanical factors supervene, they cause overdistention, so that the developmental defects become clinically manifest. Localized abnormal air spaces should therefore be looked on as overdistended defects of developmental or pathological origin. The real problem here is the primary factor that makes this lung defect subject to mechanical overdistention. In the interpretation of air space abnormalities, this has been given little consideration.

[5] Ayers, W. B.; Stowens, D., and Ochsner, A.: Fibrocystic Disease of Pancreas, J. A. M. A. 142: 7 (Jan. 7) 1950.

Problem of Emphysema as the Key to Abnormal Air Spaces.—Pulmonary emphysema has become the key to the origin and nature of abnormal air spaces. Its prevailing concept is that of mechanical overdistention of air spaces, and since abnormal air spaces are mechanically overdistended, they are considered to be manifestations of emphysema. In localized forms, check valve obstruction of the bronchi is presumed to play the key role. In diffuse forms, generalized bronchoconstriction is considered as the primary factor. Yet it has long been recognized that localized, as well as diffuse, forms of emphysema are often present without bronchial obstruction. Giant bullae in both lungs are often observed in persons showing no signs of bronchial obstruction clinically, and this cannot be demonstrated in all cases in which resection is performed. In so-called senile emphysema there may be extensive emphysematous changes that are in no way different from those of much lesser degree with bronchial obstruction, but there may be no evidence of bronchial obstruction. In all forms of emphysema there are found areas showing only merging of air spaces by traceless disappearance (atrophy) of partitions, and the air spaces so formed are abnormally large but not hyperinflated. In other areas there may be evidence of mechanical hyperinflation with disruption of partitions, compression, and displacement of adjacent lung areas. Here also there is usually evidence of local obstructive factors playing a role in their localization. It is well recognized that extensive emphysematous changes may remain clinically latent without obstructive manifestations, but the advent of obstruction makes much lesser degrees of emphysema clinically conspicuous. There is ample clinical and pathological evidence to show that air entrapment behind check valve obstruction does not satisfactorily account for more than the excessive hyperinflation of abnormal air spaces. Before this mechanical distention occurs, abnormal air spaces form by coalescence of normal air spaces by loss of partitioning, the essence of true emphysema.

In most recent literature indications now appear of beginning awareness of the problems of true emphysema. Churchill,[6] Head,[7] and Lengenhagen[8] have recently made important contributions to this. Describing observations on the physiological function of lung segments, Churchill discusses the nature of abnormal distention of air spaces in segmental lung areas and offers the concept of "space occupying function of air" as an answer to the problem of segmental emphysema. Head recognizes the fact that obstruction does not play the role generally attributed to it in the origin of emphysema itself and offers a new theory of pulmonary mechanics, explaining the development of emphysematous changes (cysts, bullae) by persistent expansion associated with loss of pulmonary elasticity. Lengenhagen contends that, even in presence of bronchial obstruction, the latter is not responsible for the distention of the affected air spaces. He attributes it to a hitherto unrecognized principle of pulmonary dynamics recently demonstrated by him. These concepts point up the complexity of the problem of diffuse emphysema and especially that of the origin of localized abnormal air spaces. In our opinion these concepts fall far short of solution, because they too look on emphysema as mechanical. The concepts advanced up to now are all based on the assumption that the lung structures behave like lifeless rubber.

Problem of the Common Denominator of All Air Space Abnormalities.—From the foregoing observations it is obvious that the ultimate problem is that of the primary factor in all air space abnormalities, including emphysema. The solution to this problem lies in a concept that can include all manifestations and can reduce them to a common denominator. There is need for a concept that will afford an explanation of localized bullous or cystic changes in otherwise normal lungs as well as diffuse pulmonary emphysema involving both lungs. Such a concept should explain on the same principle acute emphysematous changes of developmental or pathological origin as well as chronic diffuse pulmonary emphysema of undetermined origin (essential emphysema). It is our conviction that such a concept should be based on biological and not on mechanical principles of lung function. It is our belief that such a solution is available in our concept that looks on these changes as manifestations of air space disorder. If we accept this as a working theory, we may define air space disorder as a loss of air space partitioning due to lack of alveolar structure in lung defects of developmental or pathological origin. The normal expansion of the chest and lungs exerted upon such defects will result in air space disorder, that is, production of abnormal air spaces. Our concept implies that air space partitioning is part of the visceral function of normal lung structure. Therefore, air space disorder expresses a disturbance of the normal visceral function.

A full discussion of this truly biological concept of lung function is beyond the scope of this presentation. Suffice it to mention here that it was first proposed some years ago by one of us[9] and that a great deal of inferential evidence in physiological studies on lung function has accumulated since then that favors the existence of such a visceral function. A full discussion of the present status of this concept is planned for a forthcoming publication.

PRACTICAL ASPECTS

The practical implications of our concept exist chiefly in affording reasonable explanations for the clinical manifestations and a theoretical basis for new avenues of approach in treatment.

An outstanding clinical feature of air space disorder is its frequent presence without clinical manifestations when the roentgenographic evidence is most marked; contrariwise, it may be clinically most conspicuous when the roentgenographic evidence is discernible only with great difficulty. Localized air space disorder conspicuous by roentgenogram involving a large part of one lung or even both lungs may be present with little disturbance in the visceral function as a whole. In contrast, diffuse air space disorder that is barely demonstrable by roentgenogram may involve both lungs as a whole and lead to severe disturbance of visceral lung function. Localized, as well as diffuse, air space disorders even involving extensive lung areas are for the most part well compensated for by available intact lung parenchyma, affording adequate visceral function. This compensatory function is, however, readily interfered with by bronchial obstruction which leads to mechanical hyperinflation of localized air spaces or by excessive bronchospasm, which depresses the efficiency of ventilation of compensating lung areas. Clinical observations indicate that such compensation eventually becomes associated with increased expansion of the chest and lungs and increased bronchomotor activity. With increasing air space disorder, as pulmonary insufficiency is approaching bronchospastic phenomena often become clinically manifest. Dyspnea supervenes as an expression of pulmonary insufficiency. The clinical picture then assumes asthma-like features, indicated in the term pseudoasthma. The medical treatment of clinically manifest air space disorder consists essentially of combating pulmonary insufficiency and bronchospasm and of keeping the airways open.

[9] Miller, J. A., and Rappaport, I.: Relation of Pulmonary Function Fibrosis and Emphysema, Ann. Int. Med. **11**: 1644 (March) 1938.

In the foregoing discussion it was shown that obstructive hyperinflation of lung areas affected by air space disorder is a frequent complication interfering with compensation of adjacent functioning lung areas.

Modern thoracic surgery now allows us to meet this situation by resecting lung segments so affected and making available functioning adjacent lung areas free for compensatory function. The prerequisite for such surgical intervention is, of course, an accurate estimation of the affected areas and the available functioning ones. The assessment of the extent of pulmonary involvement and of available functional reserve before surgery is most difficult and requires all examinations, including planigrams, angiograms, bronchograms, and double bronchospirometry studies. Long clinical experience and close cooperation between medical and surgical consultants is necessary.

SUMMARY

Clinical and pathological observations have shown that air space abnormalities described as cysts, bullae, and pneumatoceles are common and are probably increasing in frequency. They are practically always acquired in origin and are closely related to, or in fact are in the nature of, emphysematous changes in the lung. These observations have pointed up the need of explaining both abnormal air spaces that frequently show morphological features of developmental origin and the variable forms of air space abnormalities on the basis of prevailing concepts of emphysema. Our analysis indicates that current concepts do not afford an adequate explanation of these changes.

A new concept is proposed that looks on all these, including all forms of emphysema, as forms of air space disorder. This is interpreted as a disturbance of the visceral function of the lungs. The practical implications of this concept are briefly related.

THE ESOPHAGUS IN GENERAL PRACTICE

Philip Thorek, M.D., Chicago

No specialist can claim the exclusive right to treat a specific organ or part of the body. The esophagus is no exception to this fact. The general practitioner, who almost always sees the patient first, is particularly aware of the importance of the proper interpretation of signs and symptoms. It is incumbent on every physician to be intimately conversant with the numerous manifestations that may be of esophageal origin. It is indeed embarrassing to misinterpret cardiospasm as coronary disease, to overlook a hiatus hernia as the cause of an "idiopathic" secondary anemia, or to consider the cyanosis of a newborn infant as due to a tetralogy of Fallot rather than a tracheoesophageal fistula. These errors are becoming less frequent as we learn more about the esophagus.

CARDIOSPASM

Cardiospasm is characterized by dilatation, hypertrophy, and tortuosity of the esophagus. Theories as to the cause of cardiospasm are numerous and nebulous and will not be discussed; however, it is sufficient to say that there is no known pathological origin of the condition. It is twice as common in women as in men, and in a large percentage of cases a history of emotional strain or psychic trauma can be elicited. Cardiospasm is the cause of 20% of all cases of dysphagia.

The outstanding symptoms are dysphagia, regurgitation, and retrosternal pain. Complete esophageal obstructions of varying duration, even to a point where the patient cannot swallow his own saliva, have been noted. Difficulty in swallowing is associated first with liquids and then with solids. The retrosternal pain varies from mild to severe, and prolonged use of morphine for relief may result in addiction to the drug.

Kramer and Ingelfinger have described the methacholine (Mecholyl) chloride test as an aid to the diagnosis of cardiospasm. When this parasympathomimetic drug is injected into normal persons there is only a slight increase in tone and magnitude of esophageal contractions. In patients with cardiospasm, however, marked esophageal spasm and contractions follow administration of the drug. Roentgenograms and esophagoscopy confirm the diagnosis. It is well to remember that in cardiospasm the esophagus is markedly dilated; in carcinoma it is moderately dilated; and in strictures it is mildly dilated.

Complications that may be associated with the condition are bronchitis, bronchiectasis, and pulmonary

abscess, all of which can be caused by aspirated matter regurgitated from the esophagus.

Medical management includes use of psychotherapy, antispasmodics, and dilatation. Many surgical procedures have been advised, including cardioplasty, cardiomyotomy, resection, and anastomosis.

ESOPHAGEAL SPASM AND TENSE ESOPHAGUS

Esophageal spasm and tense esophagus are overlooked or misdiagnosed frequently. The condition is a functional derangement of the esophagus that is a somatic expression of psychic disturbances and is manifested primarily as an increase in muscular tonus in the absence of local organic pathology. It should not be confused with cardiospasm. Tonus is the muscular tension present in the noncontracting state or during diastole. Esophageal muscular tonus produces pressure in the lumen; hence this pressure varies according to the state of relaxation, and esophageal pain may be produced by increase of muscle tonus. Transit times can be temporarily slowed in some persons by emotional tension.

States of diastole involve different levels and have a wide range of severity. The term globus hystericus probably represents a mild increase in tonus in the upper esophagus. Patients with this condition should not be dismissed as neurotic but can be successfully and sympathetically treated. Tension states involving the midesophagus and the lower esophagus are associated with frequent belching, heaviness, and dull pain; these same symptoms are often mistaken as signs of gallbladder disease or gastrointestinal pathology. In the severe forms there is usually excruciating substernal or epigastric pain accompanied by dyspnea, pallor, sweating, and syncope. If these are erroneously associated with coronary disease an unnecessary cardiac cripple may result. It has been proposed that the term tense esophagus refer to increased esophageal diastole and that the term esophageal spasm be reserved for the more acute and severe attacks found in patients with a tense esophagus.

Every case of tense esophagus must be thoroughly investigated before a purely functional etiology is accepted. Overlooked cases of this type impress us with the truism —when the treatment does not work, do not condemn the therapy but suspect the diagnosis. General treatment for tense esophagus is the same as treatment of functional derangements elsewhere in the body. In severe or refractory cases medical therapy and bouginage almost always result in rapid and dramatic relief.

ESOPHAGEAL DIVERTICULA

Diverticula of the esophagus can be classified in two ways; by location and by structure. As to location, there are three locations, namely, upper (pharyngoesophageal), middle, and lower (epiphrenic). With regard to structure, if a section of mucous membrane herniates through the muscle layer it is a pulsion diverticulum, but if all layers of the esophageal wall are pulled to form the pouch it is known as a traction diverticulum. The so-called traction type is usually located in the region of the bifurcation of the trachea where chronically inflamed tracheobronchial lymph nodes are found. These diverticula rarely produce symptoms since they usually have a wide ostium that forms their neck. More important than classification is the pathological physiology, which explains the signs and symptoms. A weakness in the muscular wall is believed to be a prerequisite for a pulsion diverticulum. No symptoms are produced as long as the opening into the diverticulum is large.

As food slowly packs into the pouch it increases in size and drops downward. This process continues until the weighted diverticulum produces pressure on the esophagus, causing obstruction. It should be noted that in such fully developed diverticula food has easier access to the diverticulum than to the esophageal lumen. Dysphagia is the chief symptom and diverticulitis, perforation, and mediastinitis are common complications. Roentgenograms and esophagoscopy confirm the diagnosis.

In this day of chemotherapy, improved surgical technique, modern anesthesia, and proper postoperative care, the one-stage diverticulectomy is preferred to the two-stage operation. Diverticulopexy also has its place. This procedure in which the diverticulum is dissected free and is stitched upward to the surrounding structures is reserved for the poor risk patient who has symptoms. After the operation food does not have access to the hanging diverticulum, and the symptoms are alleviated.

ESOPHAGEAL VARICES (PORTAL HYPERTENSION)

A ruptured esophageal varix results from increased pressure in the portal system (intrahepatic or extrahepatic) and is almost always found at the lower end of the esophagus. The usual cause of intrahepatic block is cirrosis of the liver, and as long as cirrhosis continues to be a common disease esophageal varices will continue to be a threat to life. Extrahepatic block may be caused by phlebitis, thrombosis, fibrous stenosis, or cavernomatous transformation of the portal vein; it may be congenital or acquired. Differential diagnosis of gastroduodenal ulcer and an esophageal varix often challenges the physician's diagnostic ability. The cirrhotic habitus (the man with no hair on his chest) and the presence of gynecomastia and telangiectasia are often signs of liver abnormality. Banti's syndrome is characterized by splenomegaly, anemia, esophageal varices, ascites, and leukopenia. If the block is due to an intrahepatic lesion, results of liver function tests will be abnormal, whereas if the portal block is extrahepatic, results are usually normal. If the disease is in a quiescent stage it might be safe to take an esophagram, which would reveal the pathognomonic "beaded" appearance at the lower end of the esophagus.

Since hemorrhage from a ruptured esophageal varix may be rapidly fatal, definite measures must be taken to prevent a recurrence. Some of the therapeutic procedures advocated are injection of the varix with sclerosing agents, tamponade through the esophagoscope, ligation of the coronary vein, esophagogastric resection to remove the "diseased" area, and the various forms of portacaval shunts. This last procedure has become popular in the past few years, and various types of anastomoses intended to shunt the blood from the portal to the caval system have been attempted. More recently, splenic and hepatic artery ligations have been advocated.

ESOPHAGEAL HIATUS HERNIA

An esophageal hiatus hernia is a type of diaphragmatic hernia in which the upper part of the stomach herniates through the esophageal hiatus. Three types of esophageal hiatal hernias have been described: the paraesophageal type, in which the stomach herniates through the hiatus and lies parallel to an esophagus of normal length; the sliding type, in which the stomach is herniated through the hiatus but has pushed an esophagus of normal length upward, rendering it tortuous; and the hiatal hernia with a congenitally short esophagus, in which the upper part of the stomach is herniated through the hiatus because the esophagus has never attained its normal length. The last type can be diagnosed by the appearance of gastric mucosa at an unusually high level. Hiatal hernias may be a coincidental finding in routine gastrointestinal roentgenograms. Such hernias rarely, if ever, produce any symptoms. Although many advocate no treatment, the danger of strangulation with resulting putrid empyema and rapid death is always present. On the other hand, many patients with hiatal hernias complain of epigastric distress, bloating, belching, anorexia, loss of weight, and retrosternal pain. Such cases have been diagnosed erroneously as gallbladder disease, peptic ulcer, gastritis, or coronary disease. These errors can be avoided if esophageal hiatus hernia is kept in mind, particularly if roentgenograms are taken with the patient in the Trendelenburg position, which would readily demonstrate an otherwise missed herniation.

Left phrenic nerve avulsion should always be considered, since it may relieve pressure and symptoms by relaxing the left side of the diaphragm. Surgical repair of a paraesophageal or a sliding type of hernia is simple, since all that is necessary is a reduction of the herniated stomach and tightening of the esophageal hiatus. Hernia with a congenitally short esophagus is the most difficult to treat successfully.

CONGENITAL DEFECTS

Much has been learned recently about congenital atresias and tracheoesophageal fistulas, so that they now can be properly classified and treated. Various combinations of these anomalies are possible. The most common defect is that in which the proximal end of the esophagus ends as a blind pouch and the distal end joins the trachea to form a tracheoesophageal fistula. Such a defect is suspected if the newborn infant has a symptom complex of coughing, choking, and cyanosis, especially with an abnormal amount of drooling and/or rhinorrhea. These cases should be considered emergencies, as the child may die of aspiration pneumonia. The roentgenologist may determine the type and site of such lesions by merely noting the presence or absence of gas in the stomach and bowel and by injecting a small amount of iodized oil (Lipiodol) through a nasal catheter into the proximal esophagus. Barium injections should never be used. If these few pertinent facts are kept in mind, every "blue baby" will not be considered to have a tetralogy of Fallot, and immediate and proper therapy can be instituted. Treatment of congenital esophageal defects is by surgery, and with modern methods a high percentage of cures can be expected.

CARCINOMA OF THE ESOPHAGUS

A defeatist attitude can no longer be assumed with regard to carcinoma of the esophagus. What was considered a hopeless and inoperable condition only a decade ago is now regarded as worth every effort. An early diagnosis is of paramount importance for increasing the survival rate in esophageal carcinoma. It may be said that any change in the swallowing habit that persists is a symptom of carcinoma of the esophagus until proved otherwise. If this dictum were followed and such symptoms further investigated by means of esophagoscopy and roentgenographic study, many esophageal neoplasms would be found and treated earlier.

Dysphagia is usually the first symptom, and the patient changes his eating habits progressively from steak to hamburger, to soft foods, and finally to liquids. There may be periods during which the patient believes the difficulty has passed. Although a tumor may involve a great portion of the circumference of the esophagus, symptoms may be minimal because of the distensibility of the remaining normal esophageal muscle. Pain and regurgitation are later manifestations. Esophagoscopy with biopsy is the only method by which a positive diagnosis can be made. The preferred treatment is surgical; irradiation therapy is of palliative value.

SUMMARY

The importance of being "esophagus conscious" has been stressed. Some common errors in diagnosis of esophageal conditions are discussed. When therapy fails to relieve a given condition one should doubt the diagnosis rather than condemn the treatment.

25 E. Washington St.

Human Factors in Sanitation Programs in Africa.—In general the primitive African is very close to nature and the realities of life and death. Disease and misfortune are familiar experiences and come unaccountably like bolts from the blue. He feels that whatever stability and strength he has comes from the fact that he is part of a larger organism and that he can only preserve this modicum of power by playing most meticulously his special part in this organism. This attitude governs his whole life and results in extreme conformity to tradition, conservatism in thought and fear of innovation. In the absence of any general conception of the inherent nature of cause and effect, he regards the workings of fate as arbitrary and haphazard and, provided he has obeyed the traditional rules, he rarely blames himself for his failures or misfortunes, but is apt to attribute them to the anger of some external agency and believes himself bewitched. Since his rules of behaviour only apply within his group, and in relation to his clan land, and since he has no abstract codes, he is left without a guiding star when he leaves his tribal sphere. . . . The success of programs of social, health, or other development will depend largely on the degree of understanding with which the basic elements are presented to the African. In no field will this be more important than in that of environmental sanitation which, striking at the very root of his existence, whether in the tribe or in the rural or urban community in which he has made his life, may be most difficult for him to accept. Precipitate action must be avoided at all costs and a step-by-step approach developed. Yet the pressing fact remains that the future development of the continent may well depend to a large extent on the success achieved in raising environmental sanitation standards.—J. W. Wright, Some Human Factors in Sanitation Programs in Africa, *American Journal of Tropical Medicine and Hygiene,* July, 1953.

METABOLISM IN PARAPLEGIA

W. James Gardner, M.D., Cleveland

The paraplegic patient often has been dismissed as one of the unfortunate by-products of war or accident and thereby often has been the victim of neglect and ignorance. The large number of persons with paraplegia resulting from World War II injuries necessitated establishment of paraplegia centers where patients were rehabilitated as fully as possible. It soon became evident that the primary problems in these long-term patients were directly related to metabolic changes caused by their condition. Many of these changes had been noted in paraplegic patients in civilian life, but the small opportunity for study of large groups of patients often prevented the development of thought and investigation of these problems.

In recent years there has been widespread reemphasis and realization of the importance of metabolism and its changes. It has been found that many of the metabolic changes heretofore apparently limited to the paraplegic person are nonspecific changes that may be produced by any form of trauma. While paraplegia is commonly accepted as being of traumatic origin, functional transection of the spinal cord caused by disease or illness results in a similar pattern of metabolic change.

In this paper metabolic changes in paraplegic patients are examined in the light of recent knowledge, with the hope that better understanding of these changes will lead to more successful management. Occasional reference is made to specific cases, seen in the neurological surgery department of the Cleveland Clinic, to illustrate certain metabolic changes and their consequences.

CLINICAL COURSE OF PARAPLEGIA

The neurological changes occurring in the course of recovery from transection of the spinal cord may have little direct metabolic consequence; however, the resultant neurophysiological changes may have much to do with the alteration or aggravation of the metabolic changes. Riddoch,[1] in his classic description of the reflex activity of the paraplegic patients in World War I, included as the last stage in the clinical course the stage of gradual failure of reflex activity brought about by toxic febrile complications. Kuhn,[2] discussing patients of World War II, does not acknowledge the existence of such a stage. Such have been the advances in the knowledge of the paraplegic person and his metabolism. The present concept of the clinical course of paraplegia includes the following stages.

Stage of Flaccidity.—This stage is characterized by complete suppression of reflex activity below the level of spinal cord injury by "spinal shock," decreased myotatic irritability, dry skin easily made erythematous by pressure or scratching, distention of the bowel and retention of urine, and rapid heat loss from the denervated area. "Spinal shock" is the period of reflex suppression, which may vary considerably, from the condition of acute traumatic shock to the more subacute and even chronic periods of metabolic change. This period averages six weeks after the initial transection of the spinal cord, until there is evidence of returning reflex activity. A few cases of a much more prolonged period of "spinal shock" have been recorded,[2] and in several of the cases seen at the Cleveland Clinic the "spinal shock" period was from six to eight months long. During this period certain metabolic changes may be profoundly altered or may fail to reverse to normal as long as "spinal shock" continues.

The period of metabolic shock that follows acute transection of the spinal cord is a definite period during which profound body changes may occur. The term "shock," however, is rather general and may mean either traumatic or surgical shock, "spinal shock," or the acute shock phase of the alarm reaction of Selye.[3] The first stage of his general adaptation syndrome is the alarm reaction, which in turn is characterized by the shock phase and the subsequent countershock phase. The shock period discussed here, varying from a few minutes to 24 hours, in general corresponds to Selye's shock phase. Transection of the spinal cord in experimental animals has been shown to produce a typical alarm reaction, although the environmental temperature may mitigate the response.[4] Complete absence of symptoms of the alarm reaction may be possible if the body temperature is maintained by artificial means. When it is not, there is a characteristic drop in the body temperature.[5]

In the shock phase there is an acute vasodepression period, which may never advance to the surgical shock level if good nursing care is maintained. There is evidence of impaired circulation resulting from marked reduction in the total number of red blood cells, the hemoglobin, and the red cell volume, and a slight reduction in the total blood volume.[6] Varying degrees of hemoconcentration may make these changes less evident.[3] The causes of these changes include trapping of the red cells in the capillaries, an increase in the plasma volume, an increased red cell destruction of indefinite etiology, and retardation of hemopoiesis due to the fall in blood pressure and in spite of the stimulus of decreased oxygen tension. The blood clotting time shows a definite decrease, with an equal acceleration of fibrin formation. The platelet count rises, as does the globulin content of the plasma, at the expense of the albumin content.[7] These circulatory dynamic changes are not as profound as those seen in other types of trauma because of the lack of certain nervous factors furnished by the intact spinal cord.[8] The latter are not deleterious nervous impulses but are normal functions of the nervous system in response to an alarm stimulus.[9]

There is a general depression of cellular metabolism with a fall in the basal metabolic rate roughly propor-

tional to the degree of the shock, although the respiratory quotient rises.[10] Some of the factors responsible are anemia, hypoxia, pain, and the loss of body heat. Nitrogen metabolism shows an early retention, but the nitrogen balance soon becomes definitely negative due to the catabolic effect of the shock phase. The blood urea, amino acids, and polypeptides likewise show early retention. Urinary excretion of creatine is augmented, although the blood creatine rises.[11]

There are similar changes in electrolyte metabolism. The potassium content rises in the blood and tissue fluid because of cell destruction and shows a similar increase in the urine. There is a pronounced decrease in the blood chlorides and in the chloride content of the tissues in general, although the chloride content of the brain and the muscles usually increases considerably above the normal level. Blood sodium decreases according to the chloride fall, as does the urinary excretion of chlorides. Blood phosphate level is elevated during the shock phase.[12] The change in carbohydrate metabolism is reflected by elevation in the blood sugar. Ketone bodies in the blood also increase. There is decreased sensitivity to the effects of insulin.[13] Fat metabolism shows little change except the frequent appearance of lipid deposits in the liver from immobilization of portions of the peripheral deposits.[14]

The mechanisms underlying these rapid changes in metabolism are incompletely understood at present. It is believed, however, that the alarm stimulus or damaging agent (perhaps through a hypothetical toxic metabolite produced under its influence) acts on the anterior lobe of the pituitary and stimulates it to discharge adrenotropic hormone. This in turn stimulates the adrenal cortex to produce an excess of corticoid hormones, which helps raise the resistance of the body and elicits the characteristic phenomena of the alarm reaction. These changes bear a striking similarity to those elicited by an overdose of adrenocorticotropic hormone.[14]

Return of Reflex Activity.—These stages in the clinical course of paraplegia advance from the return of minimal activity of the superficial genital reflexes, through varying degrees of flexor activity, to a pronounced degree of extensor activity. After the immediate responses of the body metabolism to the trauma of spinal cord transection, as characterized by the shock phase, there is a reversal of many of these responses. Selye[3] terms this the countershock phase. As the body tends to counteract the trauma and build up resistance, the countershock phase gradually merges into the stage of resistance, the second stage of Selye's general adaptation syndrome, and specific resistance reaches its peak. This period of the building of resistance will be discussed in considering the postshock period.

During this period the body temperature rises 2 to 3 degrees F, paralleling the increase of nitrogen in the urine. There is blood dilution with an increase in the total blood volume, often to a level above normal. Diuresis may occur.[3] The most profound change is an abnormal loss of nitrogen. The peak loss occurs in from four to eight days.[11] Electrolyte changes occur with an early hyperchloremia in the countershock phase. Potassium is retained to some degree, although the blood level and urinary excretion are high. The peak excretion occurs in from three to four days. The blood sugar, which may have fallen if the shock phase was prolonged, rises during the countershock phase and may reach hyperglycemic levels even if there has been no food intake. These levels may exceed the renal threshold and glycosuria will occur.[8]

EFFECTS OF IMMOBILIZATION AND BED REST

One of the best treatments for an ill patient is bed rest, but in many cases it eventually may do more harm than good. The paraplegic patient is as likely a candidate for prolonged bed rest as any; however, he derives great benefit from early ambulation.

In a study of normal, healthy young men immobilized in plaster casts from the waist down, Deitrick, Whedon, and Shorr[15] found definite changes in the body metabolism. There was a progressive nitrogen loss, starting on the fifth to sixth day after immobilization and reaching its peak in from 10 to 12 days. The urinary excretion of potassium, phosphate, sulfur, and sodium increased in a proportion correlated to the amount present in muscle and correlated to the amount of urinary calcium excreted. Calcium content in the urine was doubled, and calcium in the feces was variably increased. Creatine tolerance decreased with a corresponding decrease in the mass and the strength of the immobilized muscles. The basal metabolic rates fell an average of 6.9%. Exercise tolerance was decreased, and there was a consistent elevation of the pulse rate.

The chief cardiovascular deficits that appear on immobilization are reduction in the total blood volume and a lower peripheral venous pressure with postural hypotension. The average loss in blood volume varies from 5.4 to 9.3% in several studies, or about 500 cc. for the average person.[16] Some of this volume decrease is explained by a contraction of the plasma volume, which averages 15.5%.[17] The lower venous pressure is probably attributable to a reduction in the venous return and cardiac output that cannot be overcome by function of the natural moderator reflexes. Exactly which of the several vasopressor mechanisms is at fault is uncertain.[16b]

In the normal breakdown and repair of the body tissue, there is a continual removal and replacement of collagenous fibers. In the subcutaneous tissue, around joint capsules, in muscle planes, and in other similar locations, collagen is laid down as a loose, areolar, connective tissue that allows considerable range of motion among the moving parts. During immobilization and bed rest, however, there is shortening and tightening of the connective tissue as it is laid down. The collagenous fibers form a dense, hard scar or contracture, and this fibrosis causes loss of joint mobility. The rate of replacement is not known, but there is evidence that gross changes in deposition occur in from four to five days. By the end of three weeks the collagen scar may be extremely strong, and resumption of joint mobility may be exceedingly difficult. Thus, a cycle of immobilization may be the end-result.[18]

PROTEIN METABOLISM

The importance of protein metabolism is almost self-evident, because protein is one of the most important materials of the cellular protoplasm and next to water is the most abundant body constituent. Since the primary end-products of protein metabolism in the human body are the nitrogenous waste products composed chiefly of urea, the so-called nitrogen balances are used as indices of protein metabolism. The difference between the nitrogen taken in the food and that excreted in the feces and the urine is spoken of as the nitrogen balance. When the intake and the output are equal the body is said to be in nitrogen equilibrium. When the intake exceeds the output the body is in positive nitrogen balance; when the output exceeds the intake the body is in negative nitrogen balance.

The healthy adult requires protein to replace the inevitable loss of tissue protein. If the diet contains protein in excess of the amount needed to repair "wear and tear," the nitrogen not employed for repair is excreted, and nitrogen equilibrium is maintained. In starvation, on a low protein diet, and with trauma in general, a person continues to excrete nitrogen derived from the dissolution of his own protoplasm and so goes into negative balance.[19] The significance of the nitrogen equilibrium may be misinterpreted, however, when applied to the ill, if it is used as an absolute scale of a normal protein status. As the body is deprived of adequate protein intake, its protein and caloric needs are correspondingly reduced. With each daily loss of protein and further reduction of tissue mass, an increasingly lower protein and caloric intake is required to attain equilibrium. The equilibrium reached at such a low level of intake is more indicative of hypoproteinia than of normoproteinia, and ease of attaining equilibrium may be used as a means of detecting hypoproteinia.[20] Daily nitrogen excretion of a man of average weight on a nitrogen-free diet is about 3 gm. It might be thought that nitrogen equilibrium can be reestablished by simply feeding the patient this quantity of protein nitrogen. A considerably larger quantity must be fed, however, because the amino acids required by the body are usually in different proportions than those found in the food protein. Certain electrolytes are necessary, also in proportions. Thus a relatively large food assortment must be available and must also contain the other two food principles, fats and carbohydrates, since with an exclusively protein diet it is impossible to achieve nitrogen equilibrium because of the body's energy requirements.[19]

The postshock period of protein metabolism is characterized by the loss of nitrogen. In the first two weeks after spinal cord transection the greatest nitrogen loss occurs, directly in proportion to the severity of the injury to the spinal cord. The peak loss takes place in from three to six days and may reach a maximum of from 22 to 29 gm. of nitrogen per day. From two weeks after transection until about six months later, the degree of nitrogen wastage and its duration depend upon the severity of the initial catabolic response and the patient's ability to recover. If positive nitrogen balance has not been achieved after the six month period, the patient will be chronically debilitated, with little chance for survival.[10] The average period of nitrogen loss, as evidenced by the elevated urinary nonprotein nitrogen, is from 30 to 45 days if there has been some return of the reflex activity within this period. Most of the increased urinary nonprotein nitrogen is in urea and ammonia, with a slight increase in creatine.[21]

In poliomyelitis patients with bulbar-spinal or spinal involvement and extensive paralysis, the 24 hour urinary nitrogen excretion has been found to be the single most reliable index of the catabolic process and of the transition to other phases. Patients in hypotensive shock with decreased renal output are the exception to this generalization.[22] During the catabolic period there is a fall in the serum albumin and a rise in the serum globulin. In poliomyelitis patients this reversal of the serum proteins appears to have a direct relationship to the duration and magnitude of excessive protein destruction and the severity of the disease.[23]

The catabolic process apparently is involved in the transport of protein and minerals from the body stores to the wound site, but this is hardly true in the case of immobilized normal persons, who show the same catabolism. Debilitated patients also fail to show an increase in urinary nitrogen excretion. This failure to show a catabolic reaction might be explained on the basis of acquired resistance to nonspecific trauma of long duration. It may also be explained on the basis that debilitated persons have little storage protein. Evidence indicates that some part of the cellular protoplasm is storage protein that the cells can yield without effect on their viability and that the excessive nitrogen output may arise from this storage protein rather than from essential tissue substances.[24]

Many investigators have thought the period of negative nitrogen balance is an irreversible stage, because studies have shown that with an oral intake of protein up to 100 gm. per day practically the entire nitrogen content of the protein is excreted as urea within 24 hours. Nitrogen of intravenous protein hydrolysate is utilized in much the same manner as food nitrogen, but the nitrogen of intravenous plasma does not appear in the urine. Presumably all of this protein intake is used for energy purposes and not anabolism.[25] Recent investigation, however, has refuted this concept of irreversible catabolism. If an adequate caloric intake of about 50 calories per kilogram of body weight and high protein feeding, about 500 gm. per day, are used, positive nitrogen balance can be achieved and maintained throughout the entire postshock period. Certain special methods of nutrition are often necessary to achieve this high level of feeding.[20]

During the period of catabolism, fever plays only a small role in the nitrogen loss, but infection may play a large role. The problem of infection is of particular importance in the paraplegic patient, because he is susceptible to sepsis in the genitourinary tract. Atrophy of the paralyzed extremities from disuse contributes only a small part to the nitrogen loss. In the early stage of convalescence the positive nitrogen balance may be temporarily returned to a mildly negative balance by light exercise or by fatigue.[26]

ELECTROLYTE METABOLISM

Potassium, the chief basic ion of the body cells, is the most important inorganic substance in the group of electrolytes. The body of the average adult contains about 175 gm. of potassium, all of which is in the cells except for about 11 gm. divided among the extracellular spaces, blood cells, and the blood plasma. Trauma results in cellular breakdown, as shown by the development of negative nitrogen balance. For every gram of nitrogen broken down, about 2.7 mEq. of potassium is released. This released potassium is added to the urinary excretion of the cation. The ratio of urinary excretion of potassium to that of nitrogen is about 1 to 10. The peak loss of potassium will usually occur in from three to four days after trauma.[2]

For the fabrication of protein it is necessary to have all of the essential components of the particular tissue, which means that, in addition to the required amino acids, the necessary inorganic salts, particularly potassium, must be available. Experiments in animal feeding have shown that amino acid preparations that were nutritionally adequate in the amount and the distribution of usable nitrogen produced poor growth when diets deficient in potassium were used. This seems to indicate that a minimal daily intake of potassium is necessary in the process of protein repletion.[27]

After the immediate postshock period little change takes place in the sodium and chloride metabolism, unless there is some complicating factor that produces electrolyte loss, i. e., vomiting or diarrhea. The pathological effects of potassium deficiency may be materially modified by restriction of the sodium chloride intake, for as the sodium chloride intake rises the effects of potassium deficiency increase. Alterations in sulfur metabolism parallel those of protein metabolism. Sulfur is present in the body largely as a constituent of two amino acids, since the body does not utilize inorganic sulfur in manufacture of body protein. The ratio of sulfur excretion to nitrogen excretion is about 1 to 14 gm. Thus, during the period of negative nitrogen balance, the urinary excretion of sulfur is high. During protein anabolism a minimal daily intake of sulfur is necessary for protein production. This is furnished if the diet contains the necessary amino acids.[28]

CALCIUM AND PHOSPHORUS METABOLISM

Alterations in calcium and phosphorus metabolism are largely caused by the bone changes that occur as a result of the immobilization and bed rest. Although bone is rigid and seemingly permanent, it is really a dynamic tissue that is broken down and rebuilt continuously. Local stress and strain dictate the areas where new bone must be built. In the absence of stress and strain there is a decrease in the activity of the osteoblastic cells. The decreased formation of the organic matrix, but with a continuation of the normal osteoclastic activity of bone resorption, leads to demineralization and osteoporosis. The mechanisms for the homeostasis of calcium and phosphorus in the blood remain the same; hence they are present in normal amounts in the serum but are definitely increased in the urine. The amount of ionized calcium usually increases with recumbency.[29] The hypercalcinuria and hyperphosphaturia exist for at least the first 60 days after immobilization. The excretion level stabilizes after about 30 days and may remain so until mobilization occurs.[30]

HORMONE METABOLISM

The characteristic pattern of metabolic response to trauma is largely set by hormonal action. As mentioned before, the theoretical chain of events is from pituitary stimulation to adrenal cortical outflow, since many of the changes bear a striking similarity to those elicited by an overdose of adrenocortical hormone.[13a] Exposure to stress increases the tissue utilization of adrenocortical hormone, thereby decreasing the effective blood level that activates the anterior lobe of the pituitary to elaborate the adrenocorticotropic principle. The adrenal cortex and its secretions are particularly responsible for the control of protein metabolism and the excretion level of the urinary nonprotein nitrogen. Administration of these hormones in excessive amounts can cause an increase in the urinary nitrogen excretion; however, in animals in which the adrenals are replaced by a constant dose of cortical extract, trauma is attended by the same nitrogen excretion. Thus no increased adrenal secretion is necessary. For 24 to 48 hours after trauma, the urinary output of 17-ketosteroids is increased; then it falls below normal levels for a period approximating that of the catabolic reaction. Secretion of urinary cortin-like substances is increased for the same length of time. Perhaps the necessity of the presence of adrenocortical hormones for the protein metabolic response is based upon the potentiation of the thyroid gland in its control of nitrogen, since an increase in urinary nitrogen excretion results from the administration of thyroxin, an amino acid of the thyroid. A hormonal cause for the failure of debilitated patients to show a catabolic reaction is suggested by the fact that chronic underfeeding in rats produces a pseudohypophysectomy.[21]

COMPLICATIONS AND THEIR METABOLIC RELATIONSHIP

Decubitus Ulcer.—The decubitus ulcer is a common complication of paraplegia and can be one of the most distressing problems in the patient care. The incidence of ulcers in paraplegic patients varies from 95% in war cases to 28% in civilian cases.[31] Poer [32] found that 57% of war injury paraplegic patients at general hospitals in the U. S. had decubitus ulcers. The incidence of ulcers in paraplegic patients at the Cleveland Clinic during the past six years was about 46%.

Munro's theory[33] on the etiology of the decubitus ulcer is that the prolonged pressure on a single point leads to local tissue anemia. The normal skin maintains the vascular reflex, bringing more blood to the periphery of the pressure point. There is an absence of autonomic reflex function as well as somatic reflex function in the stage of "spinal shock," and after recovery of reflex function there is always some impairment in the functional efficiency of the autonomic responses, particularly those of piloerection, sweating, and vasomotor tone.[34] This autonomic impairment is further evidenced by the fact that in about 54% of the paraplegic patients with decubitus ulcers the spinal cord lesion is in the thoracolumbar area where the autonomic centers and outflow are concentrated. The ulcers are found in 20% of patients with lesions of the cervical cord and in 18% with lesions in the cauda equina.[31b] Since there is no increase in oxygen-bearing blood to the pressure point, local anoxia soon results, leading to local tissue necrosis.[33]

In addition to the local tissue changes, the factors of protein depletion and anemia are paramount in development of the decubitus ulcer. In Poer's series of paraplegic persons with ulcers, the majority had a negative nitrogen balance, and at least 74% had moderate to severe anemia.[32] Mulholland [35] reports that in a series of unparalyzed patients with negative nitrogen balance all decubitus ulcers healed when the catabolic state was reversed. Once a decubitus ulcer has developed, it will further aggravate and perpetuate the catabolic state by causing the loss of as much as 50 gm. of protein per day. Thus it is evident that protein anabolism must be achieved for satisfactory healing of the decubitus ulcer.

Anemia and Hypoproteinemia.—Anemia and hypoproteinemia often are the two most evident clinical manifestations of serious metabolic alterations in the paraplegic patient. Although there is considerable interrelationship in their metabolism, each disorder may exist totally independent of the other. The nutritional status of the paraplegic patient may have as much to do with the metabolic disorders as does the trauma itself. In Poer's survey, 74% of patients showed a serious loss of body weight averaging 42.5 lb. (21.25 kg.) per patient. The severe mental depression that many of these patients exhibited, with its resultant anorexia, was added to the inevitable changes in the protein metabolism. A moderate to severe secondary anemia was present in 74% of the same group of patients. In the absence of a significant degree of blood loss these severe anemias may be difficult to explain completely.[32]

In addition to the nutritional status and the protein catabolism, defects in iron metabolism may be brought about by impaired liver function in the acute shock and early postshock periods. The rate of blood regeneration following blood loss has been shown to depend chiefly upon the available body stores of iron, which, when depleted, are replaced slowly. Although iron is stored in many tissues, including the spleen, bone marrow, and the kidneys, the main storage depot is the liver. The mechanisms of iron metabolism in the presence of impaired liver function have been incompletely studied, but it is accepted that aplastic anemia may occur with liver disease.[36]

Hypoproteinemia is not necessarily present when the body has a protein deficiency. It has been shown that plasma proteins remained within the normal range even when there was a 25% loss of the body weight after a prolonged period of semistarvation and in the presence of symptoms of hypoproteinia such as reduced organ size, alterations in the fluid compartments and in tissue permeability, and mental changes.[20] In hypoproteinemia, for each gram of plasma protein that is lost there is an accompanying loss of 30 gm. of tissue protein. Thus, in an average size man weighing 140 lb. (70 kg.), with the loss of 1 gm. per hundred cubic centimeters in the plasma proteins, about 1,030 gm. of tissue protein are lost. These same relationships apply to the regeneration of protein during anabolism. Approximately 3.5% of the available nitrogen goes into the serum albumin and the remainder to the tissue proteins. There is relatively little change in the plasma albumin level after large doses of protein, a fact that has been too frequently forgotten in the clinical treatment of protein deficiency. In the presence of anemia the available nitrogen will first be diverted to the synthesis of hemoglobin, at the expense of tissue protein regeneration. It is extremely important to correct the anemia first by the use of whole blood.[37]

Liver Function.—Some degree of liver function impairment is a consequence of trauma, such as war wounds and surgical operations, and is particularly noted after spinal cord transection.[38]

In tests for liver function there is a definite retention of sulfobromophthalein (Bromsulphalein) sodium that may amount to as much as 18 to 40% during the first two weeks after spinal cord injury.[10] The abnormal results do not appear to be related to elevation of body temperature, loss of blood, severity of the post-traumatic catabolic reaction, or to the level of the lesion in the spinal cord. There does appear to be some relationship between the degree of retention and the severity of the injury to the spinal cord.[39] Normal function usually returns within three to six weeks if the patient is going to recover. Early ambulation has no influence on the return of normal liver function.[40] The urinary excretion of urobilinogen increases abnormally during the same period in which sulfobromophthalein retention occurs. Return of the urobilinogen level to normal parallels the sulfobromophthalein changes and is unaffected by ambulation.[38b]

The mechanism of impairment of liver function is indefinite, but it appears to be one of the many organ changes of the post-traumatic catabolism. Selye [3] describes some cloudy swelling of the liver cells and a decrease in the blood volume of the liver during the alarm reaction. Impairment of liver function has not been completely investigated, but it may be an important factor in metabolic changes such as protein catabolism and iron metabolism. It may also contribute to permanent liver changes, such as hepatomegaly and amyloidosis,[45] occasionally noted in paraplegic patients.

Bone Changes.—The paraplegic patient frequently has abnormal changes in the bones or the adjacent soft tissues in the paralyzed portion of the body. These changes are caused partly by abnormal local stimuli or the lack of stimulation and partly by the body's response to abnormal metabolic changes.

One important bone change is erosion, which is evident in 45% of paraplegic patients. Eighty-five per cent of the patients showing these bone changes also have decubitus ulcers, because there is a direct relationship between the bone and skin lesions. Bone lesions tend to develop wherever the soft tissue over a bony prominence becomes devitalized. Biopsies show subacute and chronic infection of the tissue overlying the bone with extension of the infection into the superficial layers of bone. This leads to resorption of the cortex and the underlying trabeculae, and the marrow is replaced by fibrovascular tissue. These changes are evident roentgenographically first as loss of the cortex and later as a rough, shaggy appearance of the bone surface. There is erosion and flattening of the prominences. With early repair, reshaping or molding of the prominences occurs, and, with later repair, proliferation leading to abnormal contours occurs. Joint surfaces are not involved.[42] The other important bone change is generalized osteoporosis in the paralyzed portions of the body. This is a disuse phenomenon caused by immobilization and is present in varying degrees in every paraplegic patient.

The soft tissue change of abnormal ossification occurs in about 43% of paraplegic patients and may occur rarely in a patient with a traumatic cord lesion in which function will return. All patients showing ossifications have or have had decubitus ulcers, but there is no correlation of areas that are involved by the two types of lesions. Ossifications are most frequently found near one of the larger joints, such as the hip or knee joint. Ossifications may occur in the muscles, tendons, tendon sheaths, ligaments, and joint capsules, or may be attached to the periosteum. The periosteum adjacent to ossifications shows no changes, as ossifications do not affect or arise from the periosteum. They usually form in a few weeks to several months after the injury and assume a mature trabecular pattern that tends to remain constant in roentgenographic appearance.[43] The cause of these abnormal ossifications is indefinite. Local injury with hematoma formation may explain part of the change. A neurogenic factor is involved, because these lesions are never seen above the level of the spinal cord lesion and are rarely seen in patients showing functional return of spinal cord activity. There is probably some abnormal tissue response to the altered calcium and phosphorus metabolism. Although blood calcium and plasma protein contents are the same in patients with and without the ossifications, blood phosphorus and phosphates are significantly elevated in patients with ossifications.[43a]

The effect of ambulation on these abnormal bone and soft tissue changes is profound. In a series of paraplegic patients, 12% of ambulant patients showed a mild osteoporosis, while 83% of nonambulant patients had a more severe osteoporosis. There was a 12% incidence of soft tissue ossifications of a minimal degree in ambulant patients compared to an incidence of 47% of ossifications to all degrees in nonambulant patients.[44]

Renal Changes.—The genitourinary tract is particularly susceptible to pathological alterations as a result of some of the metabolic changes and changes in the neurophysiology of the bladder due to the spinal cord lesion. Riddoch's third stage in the clinical course of paraplegia, that of decreasing reflex activity due to toxic febrile complications, was primarily based upon genitourinary sepsis.[1] Better understanding of the pathophysiology of the neurogenic bladder and use of chemotherapeutic and antibiotic agents have eliminated Riddoch's third stage from the modern concept of the clinical course of paraplegia. In World War I there was an overseas mortality of about 80% in the spinal cord injury cases, and, of these, 47% were due to genitourinary complications. In World War II there was an overseas mortality of 12%, and, of these, 1.5% were due to genitourinary complications.[45]

The most important metabolic changes that affect the genitourinary tract are those of calcium and phosphorus content. The hypercalcinuria present in all nonambulant paraplegic patients remains throughout the period of immobilization. In the immobilized patient there is usually an increase in the ionized calicum. Lowered plasma protein with normal blood calcium level causes an increase in the proportion of ionized calcium to protein-bound calcium. This increases the amount of ionized calcium available for stone formation. The recumbent position of the patient causes accumulation of sediment in the renal calices, furthering the tendency toward stone formation.[29] Renal calculi in spinal cord injuries of all types vary in incidence from 10 to 20% in different series of cases. Bladder calculi in the same series of cases vary in incidence from 20 to 70%.[45]

Various methods of diminishing the concentration of calcium in the urine, such as forcing fluids, acid ash diets, elimination of milk and fruit juices in the diet, and elevation of the head of the bed, have been advocated. The best prophylaxis is ambulation, which decreases hypercalcinuria almost immediately.[46]

Endocrine Changes.—Hormonal changes, which are an integral part of the body's response to the trauma of spinal cord transection, may have some profound effects upon the various endocrine systems and sexual functions of the body. The roles of hormonal change and of neurogenic factors after the spinal cord section have not been adequately defined. Selye [3] postulates that atrophy of the gonads of both sexes is caused by a shift in the hormone production of the pituitary, increasing the output of the adrenotropic hormones at the expense of the gonadotropic hormones.

Cooper, studying a series of paraplegic men, found that testicular atrophy occurred in over 50%.[47] Testicular biopsy studies have shown that there is arrested maturation of the germinal epithelium in at least 62% of the cases. The testicular changes had no relationship to local infections (epididymitis), duration of the spinal cord lesion, general systemic factors, degree of sexual potency, or the level of the cord lesion between C_6 and L_5. The factors of denervation of the epithelium and tropic changes secondary to the vasoparalysis of the spermatic cord and testicular vessels are possible explanations.[48]

Little study has been made of endocrine changes in paraplegic women because of the rarity of such patients. Young adult women with post-traumatic paraplegia usually cease menstruating for three to six months after injury, and subsequent flow is scanty and irregular.[39] Similar changes have been observed in patients seen at the Cleveland Clinic. In a young adult woman with paraplegia resulting from a degenerative spinal cord disease (neuromyelitis optica), menstruation did not resume until 18 months after the onset of paraplegia.

Gynecomastia has been observed in 22 to 25% of paraplegic men. No consistent endocrine abnormality has been demonstrated as the cause.[49]

SUMMARY

The present knowledge of metabolic changes in paraplegia is presented. Many of these changes are not limited to the paraplegic patient but occur as definite and consistent reactions to trauma of any form. Some specific complications of paraplegia are discussed, with emphasis on the metabolic abnormalities that underlie them. No attempt is made to discuss treatment of metabolic alterations, but the basic facts on which effective treatment depends are presented.

INCIDENCE AND CLINICAL MANIFESTATIONS OF CARDIAC METASTASES

Harry F. Bisel, M.D., Felix Wróblewski, M.D.
and
John S. LaDue, M.D., Ph.D., New York

The incidence found at autopsy of cardiac metastases in patients who died of cancer is reported in the literature to be less than 4%.[1] Pollia and Gogol[2] found involvement of the heart by metastatic disease in 29 cases among 1,450 autopsies of patients dying of cancer; Scott and Garvin,[3] 101 among 1,085; Ritchie,[4] 16 in 857; and Prichard,[5] 146 of 4,375 cancer autopsies. The disproportionate frequency of serial changes in the electrocardiograms of patients dying of cancer at Memorial Center led us to review the clinical and postmortem data of 500 consecutive cancer deaths observed between 1948 and 1950.

METHOD AND MATERIAL

The incidence of cardiac metastases in the various neoplastic diseases encountered was tabulated, and the exact site of the metastases, as well as the degree of cardiac involvement, was noted. The clinical, electrocardiographic, and roentgenographic findings were correlated, insofar as possible, with the pathological changes described at autopsy. No primary heart tumors were encountered in this series, and therefore discussion of these rare tumors will not be included. Data are based on 124 patients dying of leukemia, 69 of lymphoma, and 307 of other tumors. For the purposes of this study we include under the heading of lymphoma the following conditions: Hodgkin's disease, Hodgkin's sarcoma, Hodgkin's granuloma, lymphosarcoma (all types), and reticulum cell sarcoma. The leukemias were represented by acute and chronic lymphatic, acute and chronic myelogenous, acute monocytic, acute micromyeloblastic, and stem cell leukemia.

RESULTS

The over-all incidence of cardiac infiltration in 119 patients with leukemia of various types was 44% (52 patients). A slightly greater frequency of myocardial infiltration was noted in lymphatic leukemia (58%) than in myelogenous (40%). In acute myelogenous leukemia, occurring in 53 persons, the incidence was 42% (22 patients with cardiac involvement) as opposed to 35% (7 of 20 persons) in the chronic form, and the incidence was 59% (10 of 17) and 57% (8 of 14), respectively, for chronic and acute lymphocytic leukemia. Cardiac infiltration was found in 23% (3 of 13) of patients with stem cell leukemia and in the one patient each with acute monocytic and acute micromyeloblastic leukemia. No postmortem evidence of cardiac involvement was found in five patients with multiple myeloma. The cardiac involvement in all instances was characterized by interstitial and perivascular infiltration of the heart with leukemia cells. Occasional microscopic areas of fibrosis and myocardial necrosis were encountered.

The frequency of cardiac infiltration in 69 patients who died from lymphomas of various types was established, with an over-all incidence of 24% (17 patients). No significant differences were found among Hodgkin's disease (29%, or 4 of 14), Hodgkin's sarcoma (31%, or 4 of 13), and reticulum cell sarcoma (30%, or 7 of 23). Cardiac infiltration was found in only 13% (2 of 15) of the patients with lymphosarcoma and in none of the four cases of Hodgkin's granuloma. The type of involvement was variable in extent. Tumor cells were seen in epicardial fat, often extending into and between underlying muscle fibers. At times, massive replacement and destruction of muscle were noted.

In table 1 the incidence of cardiac metastases from visceral and cutaneous tumors is presented, with an over-all metastatic rate of 12%. These 304 patients had 62 types of malignant tumors. Cardiac metastases were found in 37 instances in 152 autopsies, representing 15 different types of neoplastic disease. In the remaining 155 patients (47 tumor types) the heart was not involved. The three commonest tumors producing cardiac metastases were carcinoma of the lung, carcinoma of the breast, and malignant melanoma. The incidence of cardiac involvement in the 12 other types of tumors varied widely and is also listed in table 1.

Three of the five patients with malignant melanoma had cardiac metastases. Scott and Garvin[3] reported cardiac involvement in 5 of 10 such patients (50%), and Moragues[6] in 4 out of 7 (57%). This high incidence, together with other reports, prompted us to augment the series by studying additional autopsies of patients who died with malignant melanoma at Memorial Center and a series of private patients collected by Dr. George T. Pack, totaling 34 in all. The distribution of metastases in these 34 patients is presented in table 2, with 15, or 44%, showing cardiac involvement. In no instance was the heart the sole site of metastases, and in almost every instance when the heart was involved widespread metastases were present elsewhere as well.

Similar data are listed in table 3 for 106 patients with cardiac metastases resulting from tumors other than melanoma. The distribution of the noncardiac metastases is essentially similar, except for the greater incidence of skin involvement in the patients with malignant melanoma. Fifty-five (89%) of the 62 patients with splenic metastases had either leukemia or lymphoma; in 11% splenic metastases were due to other tumors.

[6] Moragues, V.: Cardiac Metastasis from Malignant Melanoma: Report of 4 Cases, Am. Heart J. **18**: 579, 1939.

The sites of cardiac metastases in the 106 cases of leukemia, lymphoma, and visceral and cutaneous tumors were as follows: Pericardial involvement occurred in 27% (29) of the patients, 5.7% (3) of the 52 leukemia patients, 52.9% (9) of the 17 lymphoma cases, and 45.9% (17) of the 37 cases of other tumors. No significant differences were noted in epicardial, myocardial, or endocardial metastases in the three groups, the incidence ranging from 43 to 53%, from 30 to 46%, and from 20 to 27%, respectively. Bloody pericardial fluid was found in 3.8% (2) of the leukemia patients and in 11.7 (2) and 10.8% (4) of the lymphoma and other tumor groups. Gross evidence of tumor invasion of the heart was present in only 9.5% (4) of the leukemia group but was seen in 64.6% (11) of the lymphoma patients and in 72.9% (27) of the other tumor group. Predominant involvement of one chamber of the heart was uncommon in leukemia, with 3.8% (2) encountered in the right atrium, none in the left atrium, 9.5% (5) in the right ventricle, and 7.6% (4) in the left ventricle. In the lymphoma patients the incidence was 17.7% (3), 11.7% (2), 29.5% (5), and 5.9% (1), respectively. In the group of other tumors the right atrium and left ventricle were involved in 35.1 (13) and 40.5% (15), respectively; the right ventricle was the site of metastases in 18.9% (7) and the left auricle in only 8.1% (3). More than one chamber of the heart was involved in 3.8% (2) of leukemia patients, in 23.5% (4) of the lymphoma group, and in 32.4% (12) of the other tumor groups, with an over-all incidence of 16.8% (18 of the 106 patients).

* The brain was examined in 29 patients, with metastatic involvement found in 11 cases (38%).

CLINICAL MANIFESTATIONS

The antemortem diagnosis of cardiac metastasis has been made but infrequently,[7] and it seemed worth while to review the clinical data in the 106 patients with proved involvement of the heart by tumor. Fifty-nine patients had electrocardiograms, chest roentgenograms, and adequate clinical data to evaluate the cardiac status. The tumor diagnoses included leukemia in 33, lymphoma 8, bronchiogenic carcinoma 8, adenocarcinoma of breast 3, thyroid carcinoma 2, renal carcinoma 1, medullary fibrosarcoma of femur 1, rhabdomyosarcoma 1, gastric carcinoma 1, and Ewing's tumor 1. Thirty-eight of these 59 patients had no cardiac symptoms or abnormal cardiac physical findings (64.4%). Twelve patients exhibited symptoms and signs that could not be correlated with the presence of cardiac metastases (20.3%). In four instances there was a doubtful relationship between the clinical manifestations and autopsy findings (6.8%). In five patients (8.5%) it was reasonable to assume that cardiac symptoms developed as a result of involvement with metastatic disease.

TABLE 3.—*Distribution of Concomitant Metastases in 106 Patients with Cardiac Metastases*

Site of Metastases	No. of Patients	Percentage
Lymph nodes	103	96
Liver	82	77
Lung	65	61
Kidney	63	59
Spleen	62	58
Bone	50	47
Gastrointestinal tract	35	33
Adrenal	34	32
Pancreas	23	21
Genitourinary tract	19	18
Skin	15	14

Teleoroentgenograms were even less helpful in arriving at an antemortem diagnosis, since they were within normal limits in 50 instances as far as the heart was concerned. One chest roentgenogram showed the configuration of pericardial effusion, and this effusion was subsequently shown to be due to neoplastic involvement of the pericardium. In two other patients (3.4%) the cardiac silhouette was abnormal, perhaps as a result of the metastases. The abnormalities of the other six teleoroentgenograms (10.2%) could be more logically explained on other bases.

The electrocardiographic tracings of these 59 patients were within normal limits in 25 instances. Of the remaining 34, 9 showed abnormalities probably not related to cardiac metastases. In five such instances there was evidence of electrolyte disturbance associated with the administration of steroids. In others there was electrocardiographic evidence of myocardial and pulmonary infarc-

tion, subsequently confirmed at autopsy. Eight patients had electrocardiographic changes, the cause of which was obscure, and 17 exhibited abnormalities that were best explained by the metastatic cardiac lesions. From a glance at table 4, it is obvious that the electrocardiographic abnormalities observed were nonspecific and simply indicated the presence of myocardial disease not explainable on any other known basis. T-wave abnormalities were the commonest electrocardiographic evidence of cardiac metastases. The seven patients with low voltage and the five with ST segment deviations had pericardial and/or epicardial involvement at autopsy. It is our impression, both from this study and from the continuing search for evidence of metastases to the heart among the patients treated at Memorial Center, that frequent electrocardiograms will be of considerable value in helping with antemortem diagnosis of this complication.

Table 5 summarizes clinical manifestations noted in the 59 patients and correlates the antemortem status with the degree of cardiac involvement noted at autopsy. No significant differences were noted among the clinical, roentgenographic, and electrocardiographic findings and the size and degree of cardiac metastases. It is obvious that the number of patients in the various groupings is too small to permit any speculations.

COMMENT

The strong kneading action of heart muscle, its metabolic peculiarities, the restricted lymphatic connections, and the rapid flow of blood through the heart have been advanced as possible explanations of the relatively low incidence of cardiac metastases. Invasion of the heart occurs by embolism in the lymphatic channels or blood vessels or by direct invasion; the frequency is in the order listed even in the case of the more adjacent tumors, such as carcinoma of the lung or breast.[8] Kretz,[9] and others have shown that 75% of the coronary arterial blood flow returns to the right side of the heart via the Thebesian veins and coronary sinus, suggesting that embolic tumor cells may have a greater opportunity to lodge in the right chamber of the heart than the left. Our data lend support as far as the right auricle is concerned, but the left and right ventricles were involved with approximately the same frequency.

TABLE 5.—*Relationship of Antemortem Findings to the Degree of Involvement Found at Post Mortem*

Degree of Involvement	No. of Patients	Clinically Abnormal	Roentgenographically Abnormal	Electrocardiographically Abnormal
Slight	10	2	0	3
Leukemia	8	2	0	2
Lymphoma	1	0	0	0
Other tumors	1	0	0	1
Moderate	2	0	0	0
Leukemia	1	0	0	0
Lymphoma	1	0	0	0
Other tumors	0	..	..	..
Marked	6	1	0	2
Leukemia	2	0	0	1
Lymphoma	4	0	0	1
Other tumors	0	..	..	..

In our series of 500 autopsies, the heart was invaded by neoplastic disease in 106 instances, or 21%. This relatively high incidence is due, perhaps, in part to the inclusion of a disproportionate number of patients with leukemia or lymphoma, diseases that are associated with a high incidence of cardiac involvement. The fact that 44% of the patients who died of leukemia and 24% of those who succumbed to lymphoma had cardiac involvement is worthy of emphasis, since these diseases are, perhaps, more amenable to treatment by radiation and chemotherapeutic agents. Antemortem diagnosis of cardiac spread of these diseases might permit institution of specific therapy as well as a study of its effects on the heart involvement.

Repeated physical examination may reveal an unexplained tachycardia, a friction rub, or gallop rhythm, which, when taken together with electrocardiographic abnormalities, may permit an antemortem diagnosis of involvement of the heart or pericardium by neoplastic disease. When electrocardiograms are taken at frequent intervals and show definite changes not ascribable to any other form of heart disease, a presumptive diagnosis of metastatic heart disease can be entertained. Unfortunately, the only clue to cardiac involvement in our series of patients was suggested by electrocardiographic means and particularly by changes noted on serial tracings. Tachycardia was noted as frequently in patients without as in those with cardiac metastases. We found no single clinical picture or laboratory finding characteristic of cardiac metastases. It may be of significance that, since this study has started, suspicion of cardiac involvement by neoplastic disease has led in several instances to the premortem diagnosis of cardiac metastases at Memorial

Center for the first time. The diagnosis was suggested by over-all consideration of the patient, together with careful electrocardiographic and roentgenographic studies. Occasionally studies of aspirated pericardial fluid may reveal the presence of cancer cells and help to establish the diagnosis.[7b]

If associated cardiovascular symptoms are also present, consideration of specific therapy in the form of irradiation is in order. Thus far no published data are available regarding the efficacy of such therapy. Moreover, factors such as the stage of the disease, its prognosis, and the sensitivity of the type of tumor to irradiation will limit the number of patients suitable for specific treatment. The frequency of cardiac involvement by leukemic cells or lymphoma, however, justifies continued efforts for early diagnosis of this complication, since these diseases are generally radiosensitive. One patient with Hodgkin's sarcoma showed a return to normal of his electrocardiogram with relief of cardiorespiratory distress following x-ray therapy directed to the heart. This case will be reported in detail separately.

No data are available with regard to the time heart metastases develop in patients with uncontrollable cancer, but the fact that they rarely occur without the presence of widespread metastases is borne out by our studies. No patient had cardiac metastases alone, and in all instances the disease was firmly entrenched in other tissues as well as the heart.

SUMMARY

Cardiac metastases were noted in 21% of 500 consecutive autopsies done on patients who had died of neoplastic disease. Cardiac involvement was found in 44% of the 119 patients who died of leukemia, in 44% of 34 patients with malignant melanoma, in 33% of 27 patients with breast cancer, in 31% of 35 patients with carcinoma of the lung, and in 24% of 69 patients with lymphoma. The pericardium was involved in 5.7% of the leukemia group and was the site of metastases in 49.4% of the remainder. The incidence of epicardial, myocardial, and endocardial metastases varied from 43 to 53%, from 32 to 46%, and from 20 to 27% in the patients who died from leukemia, lymphoma, and the group of other tumors. Gross evidence of tumor involvement was found in 9.5% of the leukemia patients, and in 64.7 and 72.9% of the lymphoma and other tumor groups. Tachycardia was a nonspecific finding, being present in the same frequency in patients who died of cancer without cardiac metastases as the 106 with tumor invasion of the heart. Cardiac metastases were always associated with widespread involvement of many other organs by cancer. Metastatic involvement of the heart was associated with symptoms and physical findings suggestive of heart disease in only 8.5% of the patients. Electrocardiographic findings suggestive but by no means specific were present in 28.8% of the patients with cardiac metastases. The teleoroentgenogram suggested cardiac involvement in 6% of the patients so studied. No correlation was noted between the size and extent of cardiac metastases and the clinical manifestations of heart disease.

ANTISPASMODIC COMPOUND 08958 IN TREATMENT OF PARALYSIS AGITANS

Kenneth R. Magee, M.D.
and
Russell N. DeJong, M.D., Ann Arbor, Mich.

The many new drugs introduced in recent years to relieve the tremor, rigidity, and poverty of movement of paralysis agitans (Parkinson's disease) give testimony to the fact that no universally effective treatment for this disorder has been discovered. The introduction of trihexyphenidyl (Artane)[1] was an important advance in therapy, but its effectiveness is limited, and it has not entirely replaced the older solanaceous alkaloids, namely, atropine, scopolamine (Hyoscine), stramonium, and hyoscyamus. Initial successes with synthetic compounds, such as Rabellon,[2] which contains belladonna alkaloids, caramiphen hydrochloride (Panparnit),[3] diethazine (Diparcol),[4] and the antihistaminics, principally diphenhydramine (Benadryl) hydrochloride,[5] were encouraging, but these agents now seem to be inadequate for the majority of patients with paralysis agitans and have, for the most part, been reduced to the status of adjunct drugs. Similarly, agents tending to reduce spasticity, the curare derivatives and mephenesin (Tolserol),[6] seem to have very limited practical value in this disorder.

Perhaps the most significant observation to be made in the clinical study of paralysis agitans is that each patient's care must be strictly individualized. One patient will derive great benefit from a particular drug, while another may find that same substance entirely ineffective. Tolerance to drugs also has great individual variation. These factors emphasize the fact that, until a universally effective symptomatic treatment or cure is found, each patient's therapeutic program must be individually planned. Con-

---

From the Department of Neurology, University Hospital, University of Michigan.

Compound 08958 and the chemical and pharmacological information were furnished by the Lilly Research Laboratories, Indianapolis.

Read before the Section on Nervous and Mental Diseases at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

sequently, the greater numbers of preparations available, even though of limited range of therapeutic efficacy, the greater opportunity there is to provide a satisfactory program for each patient. Doshay[1a] recently emphasized this need for newer drugs. It is by virtue of this reasoning that the compound to be described was introduced.[7] This drug is by no means expected to replace any existing medication, but a sufficiently large number of patients have benefited from it to warrant further and more extensive study by different investigators.

CHEMISTRY AND PHARMACOLOGY

Compound 08958 is an aminopropanol with the chemical formula of 1-phenyl-1-cyclopentyl-3-piperidino-1-propanol hydrochloride. It, therefore, bears resemblance to trihexyphenidyl, the latter being 1-hydroxy-1-phenyl-1-cyclohexyl-3-piperidinopropane hydrochloride. The chemical structure is illustrated in the figure. Compound 08958 is supplied as the hydrochloride salt. It is a white crystalline solid and is extremely bitter to the taste.

Compound 08958 exhibits an activity approximately equal to that of atropine on isolated guinea pig intestinal strips stimulated with mecholyl or acetylcholine. On similar test preparations, it showed practically no antihistamine activity. In similar tests in which isolated strips of uterine muscle from the guinea pig were employed, Compound 08958 showed no effect. In trained dogs with Thiry fistulas, spasmolytic action on small intestines was about one-half that procurable with atropine when both agents were given intravenously. Effectiveness of Compound 08958 by oral administration could be demonstrated in anesthetized cats.

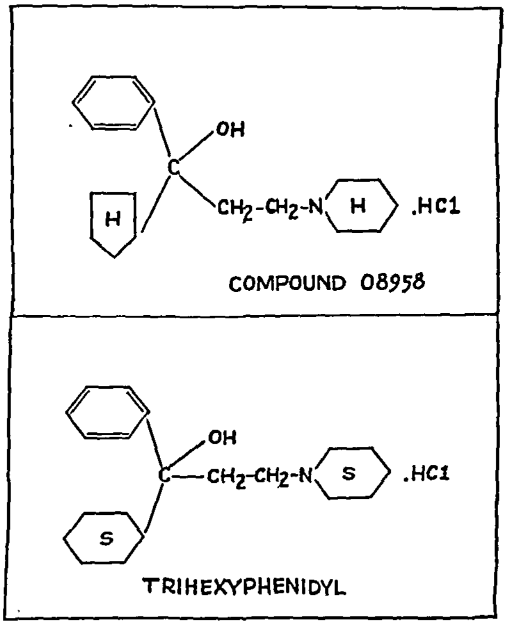
When Compound 08958 was administered intravenously in large doses to dogs, a fall in blood pressure with fairly slow recovery was observed. The manifestation was less acute with smaller doses. Respiratory stimulation followed the fall in blood pressure and was believed to be a secondary phenomenon to the hypotension.

Compound 08958 was about one-tenth as effective as atropine in blocking salivary flow in anesthetized dogs. Similarly, in anesthetized cats the drug was one-tenth as effective as atropine in blocking cardioinhibitory fibers of the vagus nerve. Mydriatic and slight local anesthetic activity could be demonstrated when solutions prepared from Compound 08958 were placed in the conjunctival sacs of albino rabbits.

Toxicity studies in rats and mice disclose Compound 08958 to be slightly, but not markedly, more toxic than atropine by either oral or intravenous administration. Chronic toxicity tests in rats over a one month period showed no evidence of damage, either grossly or microscopically.

PROCEDURE

A total of 67 patients were treated on the neurology service of the University Hospital. No selection was made as to type or severity of the paralysis agitans; each patient was accepted as he or she appeared at the clinic. It is known that it is extremely difficult to evaluate objectively the results of treatment in paralysis agitans. Even refined methods of testing fail to be conclusive in a disorder in which the patient's condition changes from moment to moment depending on his emotional reaction to coming to the clinic, the reaction to the physician and the examination, the state of fatigue, and the general physical condition. Even placebo controls mean very little when it is remembered that a patient who receives good relief from a new medication might well fail to report lack of benefit when placed on placebos, thereby admitting to himself that the new agent he had found and in which he had developed hope and faith was, in reality, worthless. In an attempt to diminish the suggestive connotations of treatment with a new drug, each patient was told that he or she was to be given a trial on several new drugs, any or all of which might help or prove worthless. In this way the patient was able to choose which of the new drugs, if any, he preferred without having to place all his faith in any one drug; he could, therefore, more realistically evaluate each medication.



For comparison the structural formulas of Compound 08958 and trihexyphenidyl (Artane) are illustrated.

To be considered useful, certain qualifications had to be fulfilled by the experimental drug: (1) it should give some degree of subjective relief to the patient's symptoms; (2) it should produce some objective evidence of improvement on neurological examination; (3) it should be as effective as the drugs already available or, if not as effective, should have some use as an adjunct

drug; and (4) the toxicity of the drug should not outweigh the beneficial effects.

The patients were thoroughly questioned regarding both their over-all impressions on the effect of the drugs and the presence of side-effects. For more critical appraisal they were asked to observe and report changes in specific daily activities, such as the alteration in the tremor while eating, dressing, shaving, or working, and to record alterations in gait, articulation, strength, and rigidity. Frequent examinations were carried out to observe changes in the tremor as brought out by improvement in holding objects, dressing, and writing. Changes in rigidity, associated movements, strength, speech, posture, and ability to perform skilled movements with greater ease and speed were similarly evaluated.

The majority of patients had taken either scopolamine or trihexyphenidyl, or both, and the effectiveness of these compounds and other drugs was noted and compared. Several other experimental drugs were used either before or after treatment with Compound 08958. If the patient reported best results with Compound 08958 after failure with the other experimental preparations, he again received it for prolonged trial.

RESULTS

The results of therapy with Compound 08958 are illustrated in table 1. Patients were divided into four groups. Group A consisted of those in whom Compound 08958 gave relief superior to that obtained by previous standard medications, trihexyphenidyl or scopolamine in the great majority, and also produced definite objective evidence of improvement on neurological examination, but did not cause significant side-effects when given in adequate therapeutic doses. Group B included those patients who found no difference between Compound 08958 and the previous medications. Objective evidence of improvement above that obtained with no treatment was essential. In group C were those patients who received some benefit from Compound 08958, but not as much as with previous medications. Patients in whom Compound 08958 was either ineffective or produced side-effects serious enough to preclude its use were placed in group D.

TABLE 1.—*Results of Therapy with Compound 08958*

Type of Paralysis Agitans	No. of Patients	Group A		Group B		Group C		Group D	
		No.	%	No.	%	No.	%	No.	%
Idiopathic	31	16	52	8	26	2	6	5	16
Postencephalitic	20	11	55	5	25	4	20	0	0
Arteriosclerotic	10	1	10	2	20	4	40	3	30
Totals	61	28	46	15	25	10	16	8	13

Of 61 patients with paralysis agitans, a total of 28, or 46%, found relief with Compound 08958 superior to that obtained with any other medication, while 15, or 25%, found no difference between the benefit of this compound and previous drugs. It was noted that patients with either idiopathic or postencephalitic disease made up the larger percentage of those in the first group (relief superior to that with other medications), the actual figures being 52 and 55%, respectively.

Table 2 shows the relative improvement in each component of the disease, using the same groups for classification as in table 1. As is true with the other atropine derivatives, rigidity was helped the most, but an unusually large number of patients felt that their tremor was materially improved.

Of particular interest are the four patients who received remarkable relief from oculogyric crises. Three of these patients have taken Compound 08958 for more than nine months with dramatic decrease in the frequency of the oculogyric attacks, but with abrupt recurrence if they stop taking the drug for several days. The fourth patient received complete relief from the attacks, but found Compound 08958 (and also its placebo preparation) so toxic that it had to be discontinued.

TABLE 2.—*Improvement in Major Symptoms After Therapy with Compound 08958*

Symptoms	Group A		Group B		Group C		Group D	
	No.	%	No.	%	No.	%	No.	%
Tremor	29	58	14	28	5	10	2	4
Rigidity	30	61	12	26	3	6	2	4
Bradykinesis	27	60	11	24	3	7	4	9
Oculogyria	4	100	..	..	..	..	..	..
Blepharospasm	..	..	1	50	..	..	1	50

Six patients in the series did not have paralysis agitans. Of these, only one patient with dystonic movements of his upper extremities obtained good results with Compound 08958. The other diagnoses were familial tremor, senile tremor, congenital athetosis, spastic pseudosclerosis, and the Hallevorden-Spatz syndrome. These patients received no benefit from Compound 08958 and experienced toxic reactions on relatively small doses.

Compound 08958 was available in 2.5 and 5 mg. tablets. Attempts were made to standardize dosage. It was evident that there was an extremely wide variation in the optimum therapeutic dose. The best results were obtained in the postencephalitic group, as is usually true when using atropine derivatives. This may well be due to the fact that these patients could tolerate much larger amounts of medication. Several patients were maintained on 30 to 50 mg. of Compound 08958 each day without apparent adverse effect. On the other hand, those with idiopathic and arteriosclerotic conditions could not tolerate the medication nearly as well. It became evident that, to secure maximum beneficial results, it was best to begin each patient on a very small dose, such as 2.5 mg. once each day, and to increase the dose by one tablet every two or three days to the point of tolerance. To patients giving a strong history of intolerance to the atropine derivatives, one-half of the 2.5 mg. tablet was given once daily; this amount was increased slowly as it was established that the patient could tolerate the preceding day's dose.

Significant side-effects consisted of dry mouth, dizziness or light headedness, blurred vision, nausea, weakness, and epigastric discomfort. In addition, the most serious side-effects of confusion and disorientation occurred early in the study when, after the initial high tolerance of the first few patients, each patient received 5 mg. tablets of Compound 08958 three times daily as a starting dose. The side-effects cleared promptly when the medication was discontinued or the dose was reduced.

Several patients who experienced severe reactions on the 5 mg. tablets are classified as poor results, although those who were again placed on Compound 08958 in smaller doses often experienced very good results. Two patients classified as poor results because of severe reactions noted the same side-effects when they were given a placebo preparation of Compound 08958. The number and percentage of side-effects are listed in table 3.

TABLE 3.—*Side-Effects in Patients Receiving Compound 08958*

Type	No. of Patients	%
Dry mouth	22	36
Blurred vision	7	11
Dizziness	15	25
Palpitation	2	3
Epigastric discomfort	5	8
Nervousness	7	11
Insomnia	1	2
Salty taste	3	5
Weakness	2	3
Nausea	3	5
Numbness	3	5
Disorientation	2	3

From this series, it is evident that a given dose of Compound 08958 is considerably more potent than trihexyphenidyl in both beneficial effect and side reactions. Twenty-one patients were known to have previously taken scopolamine, and, of these, 17 preferred Compound 08958. Forty patients were known to have taken trihexyphenidyl, and, of these, 21 preferred Compound 08958, 7 preferred trihexyphenidyl, and 12 could see no significant difference.

COMMENT

Many drugs have been introduced in the treatment of paralysis agitans with early enthusiasm only to be proved later to be of little or no value. This leads us to interpret the results obtained in this series cautiously and to keep in mind the many variables in evaluation as outlined above. Of course, final conclusions will depend on larger groups of statistics by different investigators. It does, however, seem safe to conclude that preliminary studies have demonstrated that Compound 08958 has been of value in a limited series of patients with paralysis agitans and that it should be studied further to ascertain its definitive place in the physician's armamentarium for the treatment of this disorder.

SUMMARY

A series of patients with paralysis agitans (Parkinson's disease) received a therapeutic trial with the antispasmodic, Compound 08958 (1-phenyl-1-cyclopentyl-3-piperidino-1-propanol hydrochloride). Of these patients, 46% received beneficial results superior to those obtained by standard medications. Side-effects were similar to those produced by other atropine derivatives. Careful adjustment of dosage was necessary to minimize these side reactions.

ADDENDUM

Since this article was prepared, Compound 08958 has been released by the Eli Lilly Company under the trade name Pagitane hydrochloride in 1.25 and 2.5 mg. tablets.

BLOOD AND SPINAL FLUID TESTS FOR REAGIN AFTER TREATMENT OF NEUROSYPHILIS

Evan W. Thomas, M.D., Albany, N. Y.

It has long been known that in patients treated for late neurosyphilis blood serum and spinal fluid tests for syphilis continue to give positive results for varying periods after treatment. Yet, many patients are still treated unnecessarily in the hope of reversing such positive reactions. This practice continues because few reports on the long-term follow-up of large series of patients have been published. Physicians are disturbed by the great variety of serologic responses that may be encountered in treated patients, some of whom become seronegative relatively soon while others remain seropositive for years. Even more disconcerting are the great fluctuations in titers obtained in quantitative tests and the great discrepancies in titers obtained by different kinds of tests that occur in some patients and not in others. Such serologic phenomena are not easily interpreted, but, as this report attempts to show, the persistence of reagin in varying amounts following treatment of known syphilis does not necessarily indicate the persistence of an active infection.

At Bellevue Hospital, 396 patients have been followed for more than five years after treatment of neurosyphilis with either malaria or penicillin. Neurosyphilis was chosen for the presentation of follow-up data because there was no question about the diagnosis of syphilis in patients with this complication. When first treated at Bellevue Hospital, all patients had active neurosyphilis, as shown by spinal fluid examinations. In my judgment, the neurosyphilis has been permanently inactivated in all of these patients for more than five years, despite numerous vagaries in the titers obtained in serologic tests for syphilis.

The concept of differentiating between activity and inactivity of neurosyphilis by means of spinal fluid examinations has been described by Dattner and me in numerous papers.[1] Briefly, we have shown that active neurosyphilis is best demonstrated by pleocytosis in association with positive results in specific tests of the spinal fluid for syphilis. After successful treatment, the spinal fluid cell count should become normal within three to four months and should remain normal, and there should be a more gradual improvement of results in other quantita-

---

This study was aided by grants from the United States Public Health Service.

W., and de Mello, L.: Results of Penicillin Therapy for Neurosyphilis at Bellevue Hospital, ibid. 32: 33, 1951.

tive tests of the spinal fluid. The persistence of reagin in the spinal fluid for years after treatment does not prove that the disease is active, but high reagin titers usually show a significant decline during the first year after successful treatment. The clinical manifestations of neurosyphilis are, of course, important, but, obviously, normal function of permanently damaged tissues in the central nervous system cannot be restored by the killing of spirochetes. Clinical manifestations are indications of active disease only when there is unquestioned evidence of progressive disease.

This report is not to be construed as an evaluation of the relative effectiveness of malaria and penicillin therapy. Its purpose is rather to show what can be expected from tests for reagin performed after syphilis has been arrested by treatment, as shown by spinal fluid and physical examinations. No patients in this series showed clinical evidence of progressive neurosyphilis after the last treatment.

METHOD

The period of follow-up for each patient dates from the completion of the last successful treatment, as previously defined. Over 50% of patients in both groups prior to malaria or penicillin therapy had received varying amounts of metal therapy, sometimes irregularly for years, without permanent arrest of the infection. Serologic tests for syphilis were performed, as a rule, every two or three months during the first year after treatment and at three to six month periods thereafter. Spinal fluid examinations were made in most cases three to four months after treatment and at six month intervals thereafter. The latter schedule could not be completed for all patients, but, with few exceptions, every patient had at least one spinal fluid examination each year until two completely normal reports were received, and in numerous patients the examinations were continued yearly after results of all spinal fluid tests had become normal.

Several patients in each group who had no evidence of clinical relapse or of pleocytosis were retreated for the sole purpose of noting the effect on persistently high blood serum reagin titers. In these cases, the follow-up dates from the time the patients received therapy resulting in normal cell counts and decreases in spinal fluid reagin titers. Retreatment in such case had no significant effect on the titers of either the blood serum or the spinal fluid. Not only in patients with neurosyphilis but also in those with other forms of late syphilis I have proved to my satisfaction the futility of prolonging treatment or of retreatment for the sole purpose of lowering high reagin titers.

FOLLOW-UP OF MALARIA-TREATED PATIENTS

Patients treated with malaria received 10 daily injections of 0.06 gm. of oxophenarsine hydrochloride following the last fever and no subsequent therapy except for reasons previously outlined. The malaria-treated group consisted of 183 patients who were followed for 5 to 14 years after the last treatment. Two tabetic patients in the series had negative blood serologic test reactions when treated with malaria but they had active neurosyphilis, as indicated by spinal fluid examinations. They are excluded from table 1, which gives data on the persistence of positive serologic test reactions following treatment. One patient who was followed for more than six years with serologic tests had no spinal fluid examination after the first four years after treatment. This patient is included in table 1 but excluded from table 3, which gives data on the spinal fluid tests. The entire group is classified by race and sex: white males, 122; white females, 34; Negro males, 19; Negro females, 6; and Chinese males, 2.

Serologic Test Data.—The blood serum examinations in the early years of follow-up were done with qualitative Kahn and Wassermann tests at the Bellevue Hospital laboratory. From 1943, quantitative Kahn tests were done in the New York University-Bellevue Medical Center laboratory, and quantitative complement fixation tests were done by the New York State Department of Health laboratory. Additional Kolmer complement fixation tests were done in some cases. No patient was counted as having negative test results unless the results from all types of tests used were completely negative. During a follow-up of several years' duration, negative results from one or more serologic tests are frequently interspersed between slightly positive test results, and occasionally the titers in one or more tests fluctuate greatly. Minor variations in titers are probably caused by varying sensitivity of the tests, but extreme fluctuations may be due to intercurrent infections or unknown causes. In either case, a reactivation of syphilis cannot be assumed to have occurred when positive serologic test results are reported subsequent to negative tests results or when, in the case of positive results, the titers fluctuate, unless significant increases in titers from previous levels persist for several months.

Our present ignorance of the true nature of serologic tests for syphilis is emphasized not only by fluctuations in titers but also by the frequently occurring discrepancies among titers from different tests performed on the same specimen of blood. In my experience, wide fluctuations in titers may be reported for one test but not for another, or there may be for years pronounced sustained discrepancies in the titers obtained by different tests. The occurrence of such discrepancies suggests that the reagin tested for in the blood serum is a complex substance that may consist of more than one presumed antibody or that in some persons inhibitory substances interfere with the demonstration of reagin more in some tests than in others. The wide fluctuations in titer following treatment suggest that factors other than syphilis influence the tests in known syphilitic patients as well as in persons who have biologically false positive reactions to tests for syphilis. Whatever the explanation may be for the bizarre serologic patterns noted in a prolonged follow-up of treated syphilitic patients, it is reasonably certain that, in the absence of other evidences of relapse or progression of the disease, they do not indicate continued activity of the syphilitic process, and treatment should not be continued solely on the basis of such serologic patterns.

When the patients were last examined, the titers in all except a few serologic tests recorded as positive were relatively low (positive in dilutions of 1:2 or less or in units of less than 10), but positive test results with high dilutions on at least one occasion persisted for more than two years in a number of patients, who were retreated for that reason. As previously noted, retreatment did not result in lower titers.

Table 1 shows the number of patients followed for various periods (years) after treatment was stopped, the numbers still seropositive at the designated intervals, and the number becoming seronegative each year after cessation of treatment. To obtain the total number of patients who became seronegative, the numbers becoming negative each year must be added.

To obtain a possibly more accurate estimate of prolonged seropositivity, modified life table methods were used to compute the percentage expected to be seropositive for each designated period after the sixth year of follow-up. The results are shown in table 2. Because of the relatively small number followed for more than 11 years, estimated percentages by life table methods after the 10 to 11 year period are not given. Of the patients actually followed for 10 to 11 years, 71.7% were still seropositive (table 1) as compared to an estimated 62.8% who would be seropositive if all patients had been observed for that period (table 2).

Spinal Fluid Test Data.—Spinal fluid specimens from patients treated with malaria were examined by means of the Bellevue Hospital Wassermann test during the early years of the study but subsequently were tested with the quantitative complement fixation test for syphilis that is used in the New York State Department of Health laboratory. Results of the latter test are reported in units. In my experience, it is an exceptionally reliable test but is less sensitive than the Kolmer complement fixation test. After 1948, the Kolmer test was used in addition to the New York State test for all patients in the penicillin-treated group but not for all in the malaria-treated group.

Table 3 shows the results of spinal fluid test follow-up in the same manner as results of serologic tests are shown in table 1. The bizarre serologic patterns noted in the blood serum of some patients were not found in the spinal fluid. Consequently, the reagin present in spinal fluid seems to be less influenced by unknown factors than is the reagin in blood serum. When spinal fluid reagin was found in a relatively large amount at the time of treatment, the titer invariably fell significantly within six months to a year after treatment, but it frequently remained at low levels for years without evidence of clinical progression. Patients with low spinal fluid reagin titers, when treated, often continued to have low titers for varying periods after treatment. When last examined, only six of the malaria-treated patients had spinal fluid reagin titers of more than 10 units. In general, reagin disappears more rapidly from the spinal fluid than from the blood serum, but the reverse may be true. As shown in table 3, more patients had negative results in tests for reagin in the spinal fluid than in tests for reagin in the blood serum, but the percentage of those who continued to have slightly positive spinal fluid test results for 10 years or more is higher than I anticipated.

Persistence of demonstrable reagin in the spinal fluid does not necessarily prove persistence of the syphilitic infection in the central nervous system, and it certainly does not prove failure to arrest the infectious process. My experience shows that if the spinal fluid cell count has become normal and there has been improvement in results of other spinal fluid tests for two years after treatment, the infection may be confidently expected to have been permanently arrested. At Bellevue Hospital, I have never observed relapse of neurosyphilis, as shown by an increased cell count and increases in results of other quantitative tests of the spinal fluid, more than two years after treatment, even though demonstrable reagin was still present.

Table 4 shows the types of neurosyphilis for which malaria treatment was given and gives the percentage of patients in each classification who had negative spinal fluid test results when last examined. The high percentage of negative results found in the asymptomatic group is probably best explained by the fact that most of the patients in this class were relatively young and presumably had had syphilis for a shorter time than most of the patients in other classifications; however, no patient in whom the duration of syphilis was known to be less than two years is included in this report. Age is not a determining factor in the duration of positive results in tests for spinal fluid reagin after treatment, but the duration of the infection usually is, even though occasionally patients treated for syphilis of only two years duration may have positive blood and spinal fluid test results for years after treatment.

FOLLOW-UP OF PENICILLIN-TREATED PATIENTS

For comparison with the malaria-treated series, only penicillin-treated patients who have been followed five years or more are included in this report. The penicillin dose varied from 2 to 9 million units, except in a few cases in which it was much higher because retreatment was necessary for relapse. Most of the patients received either 6 or 9 million units. Penicillin was not used to treat neurosyphilis at Bellevue Hospital until April, 1944, and treatment was started with doses that proved too low. The series followed for five years or longer consists of 213 patients. It was composed of 109 white males, 32 white females, 38 Negro males, 21 Negro females, and 10 males and 3 females who were Puerto Rican or Chinese.

TABLE 2.—*Percentage of Patients with Blood Serum and Spinal Fluid Positive for Reagin at Stated Intervals After Treatment of Neurosyphilis, Estimated by Modified Life Table Analysis*

Yr. After Treatment	% of Patients with Positive Serologic Test Results		% of Patients with Positive Spinal Fluid Test Results	
	Malaria-Treated	Penicillin-Treated	Malaria-Treated	Penicillin-Treated
6-7	81.1	72.6	53.8	62.7
7-8	78.6	66.2	49.9	61.1
8-9	75.2	....	44.8	....
9-10	71.4	....	38.8	....
10-11	62.8	....	36.0	....

Serologic Test Data.—Because all the penicillin-treated patients were studied with quantitative complement fixation and Kahn tests from the beginning of treatment, it is possible to give more accurate data on discrepancies in the titers obtained by different serologic tests and on fluctuations of titer than was the case with the malaria-treated group. At the time of treatment with penicillin, 24% had titers of 20 or less; 41% had titers between 20 and 60: and 35% had titers of 60 or higher.

TABLE 4.—*Diagnostic Classification of Malaria-Treated Patients and Percentage with Normal Spinal Fluid When Last Examined*

Diagnosis	No. of Patients	Patients with Normal Spinal Fluid When Last Examined	
		No.	%
Asymptomatic neurosyphilis	20	16	80.0
Meningovascular syphilis	54	35	64.8
Tabes dorsalis	57	33	57.9
General paresis	29	14	48.3
Taboparesis	22	9	40.9
Total	182	107	58.8

That there may be pronounced discrepancies in the results from various serologic tests in cases of active neurosyphilis is shown by the facts that, when treated with penicillin, eight patients had negative results with the Kahn test and positive results with the complement fixation test, two had positive Kahn test results and negative complement fixation test results; nine had low titers in the Kahn test and high titers in the complement fixation test (i. e., Kahn test titers of 4 or less and complement fixation test titers of 32 or higher), and 1 had a titer of 64 in the Kahn test and extremely low titers in the complement fixation test.

Following treatment, pronounced fluctuations in the titers of one or more tests occurred in 20 (9%). These results included such findings as a positive serologic test result of 4 or more units interspersed between negative test results or pronounced increases in titer with subsequent drops, e. g., increases from 4 to 64 units followed by rapid or gradual falls to previous levels. When last examined, 75 patients (35%) showed marked discrepancies in titers determined in various serologic tests, 33 had negative Kahn and positive complement fixation test results, and 2 had positive Kahn and negative complement fixation test results. The greatest discrepancies occurred between the Kolmer complement fixation test and the Kahn test. As performed at the New York University-Bellevue Medical Center, the Kolmer test was usually the most sensitive of the three, and usually its results were reported in higher units than those of the New York State complement fixation test. Examples of extreme discrepancies are those in the cases of three patients in whom the Kahn test results became negative after treatment and remained negative throughout the subsequent years of follow-up while the Kolmer test titers were never lower than 64 units. Four patients had negative Kahn test results and positive Kolmer test titers of 32 when last examined, and two had Kahn test titers of 64 and complement fixation test titers of less than 10.

TABLE 5.—*Results of Follow-Up Serologic Tests for Syphilis in Penicillin-Treated Neurosyphilitic Patients with No Clinical Evidence of Relapse or Progression of Disease*

Yr. after treatment	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9
No. followed	213	213	213	213	213	131	77	19
No. still positive	201	194	186	181	171	95	51	12
% still positive	94.4	91.1	87.3	85.0	80.3	72.5	66.2	63.2
No. becoming negative each yr.	12	7	8	5	10	10	5	0

As previously mentioned, findings such as these emphasize our present ignorance of the composition and formation of reagin in the blood serum, where its presence in some syphilitic, as in some nonsyphilitic persons, apparently is influenced by factors other than syphilis, since I had no reason to believe from clinical and spinal fluid examinations that syphilis was active in any patient. As a matter of fact, all tests for reagin are based on the principle of identifying antibodies, and, by analogy with other antibodies, it is not surprising that reagin should continue to be found in blood serum and spinal fluid long after the syphilitic infection has been arrested or cured. Also, in view of the tendency of some persons to have reagin in the blood serum (but not in the spinal fluid) from causes other than syphilis, the fluctuations in serologic test titers after treatment might have been anticipated.

In table 5 data on the serologic tests done in the penicillin-treated patients are summarized. Comparison of table 5 with table 1 shows that higher percentages of malaria-treated patients than of penicillin-treated patients remained seropositive for longer periods. This finding cannot be interpreted as necessarily implying that penicillin was a more effective treatment than malaria, since, as previously noted, persistence of reagin after treatment does not prove continued activity of the infection.

Spinal Fluid Test Data.—Only 203 patients are included in the report on spinal fluid tests in table 6, because 10 patients who were followed with serologic tests for more than five years refused to have spinal fluid examinations after the third or fourth year. Table 6 shows that, for the 5 to 6 year period of follow-up, the percentage of patients with positive spinal fluid test results is almost exactly the same as in the malaria-treated group. After the sixth year, however, lower percentages are found in the malaria-treated group. The pronounced drop in penicillin-treated patients followed after the sixth year may have influenced the percentages after the 5 to 6 year period of follow-up, but a much better explanation is available. Ten patients recorded as having positive spinal fluid test results in table 6 had negative New York State complement fixation test results and slightly positive Kolmer test results when last examined and, thus, by definition were classified as having spinal fluid positive for reagin. The Kolmer test was not done on many of the malaria-treated patients. In table 7 the various types of neurosyphilis are classified, and the percentage of patients in each classification who had completely negative spinal fluid test results is shown.

TABLE 6.—*Results of Follow-up Tests for Spinal Fluid Reagin in Penicillin-Treated Neurosyphilitic Patients with No Evidence of Clinical Relapse or Progression of Disease*

Yr. after treatment	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9
No. followed	203	203	203	203	203	125	76	19
No. still positive	187	172	155	142	129	69	40	10
% still positive	92.1	84.7	76.4	69.9	63.5	55.2	52.6	52.6
No. becoming negative each yr	16	15	17	13	13*	1*	1*	0*

* In comparing these data with those in table 3 it should be noted that three additional patients in the 5-6 year period, two each in the 6-7 and 7-8 year periods, and three in the 8-9 year period had negative results in the New York State complement-fixation tests of the spinal fluid but positive results in the Kolmer tests. The latter tests were not done on most of the malaria-treated group.

TABLE 7.—*Diagnostic Classification of Penicillin-Treated Patients and Percent with Normal Spinal Fluid When Last Examined*

Diagnosis	No. of Patients	Patients with Normal Spinal Fluid When Last Examined	
		No.	%
Asymptomatic neurosyphilis	40	27	67.5
Meningovascular syphilis	48	20	41.7
Tabes dorsalis	53	16	30.2
General paresis	41	7	17.1
Taboparesis	18	6	33.3
Spastic paraplegia	3	0	00.0
Total	203	76	37.4

Table 2 gives the estimates obtained by modified life table methods, of the probable percentages of patients who would have been found to have positive serologic test results and positive spinal fluid test results if all patients had been observed for the specified periods. When the previously mentioned variables are considered, the differences in the percentages between the malaria-treated and penicillin-treated groups are not significant. Even if they were, they could not be used to evaluate the effectiveness of treatment for the reasons mentioned.

SUMMARY

1. From data obtained in a 5 to 14 year follow-up of 181 patients treated for neurosyphilis with malaria therapy and a 5 to 8½ year follow-up of 213 similar patients treated with penicillin, it was found that positive results from serologic tests for syphilis persisted in 80 to 84% of patients followed for 5 years and in 70% of patients followed for 10 years after treatment. 2. Positive results from tests for spinal fluid reagin were found in 63% of patients followed for 5 years and in 27.7% of patients followed for 10 years after treatment. 3. The futility of retreating patients solely because of the persistence of reagin in blood serum and spinal fluid is stressed. In cases in which retreatment was given to note the effect on high titers of blood or spinal fluid reagin no appreciable change in titers was obtained. 4. During the years of follow-up, pronounced discrepancies among the titers obtained by different types of serologic tests occurred in many patients in both groups (in 35% of those treated with penicillin). Fluctuations in the titers obtained with a single type of test occurred with one or more of the serologic tests in some patients in both groups (in 9% of those treated with penicillin). 5. It is suggested that reagin in the blood serum is a complex substance consisting of more than one presumed antibody and that factors other than syphilis may influence the production of one or more of these "antibodies" in known syphilitic patients as well as in persons who have biologically false positive results in tests for syphilis. 6. Spinal fluid reagin is rarely influenced by the unknown factors that affect blood serum reagin and cause changes in serologic test results. 7. Relapse of neurosyphilis, as determined by increases in spinal fluid cell count and in results of other quantitative spinal fluid tests, never occurred later than two years after treatment had inactivated the infection.

39 Columbia St. (7).

Human Engineering.—Until quite recently it was accepted that the equipment a human operator had to use was fixed by engineering considerations only and was not thereafter open to change. Efforts to secure better man-machine performance were made by selecting operators with especially good aptitude or by giving them extensive training on the task. This is a rather wasteful procedure, because a proportion of potential operators must be rejected, because the selection process and training have to be kept going, and because, in spite of all this, the overall results may be below expectation. . . . During the second World War the need for getting efficient performance out of communication and control systems containing human operators brought into being a field of study known variously as ergonomics, biotechnology and work space design, but perhaps best as "human engineering." Human engineering is a blend of various biological sciences—physiology, anatomy, physical anthropology and especially applied experimental psychology, together with various branches of engineering. It aims to determine human capacities, to provide principles governing the design of machines for efficient human use, and to ensure an effective integration of man and machines for the accomplishment of an overall task.—J. C. Lane, M.D., Human Engineering: A New Technology, *Medical Journal of Australia,* July 4, 1953.

CLINICAL NOTES

CHLORDANE INTOXICATION

REPORT OF A CASE

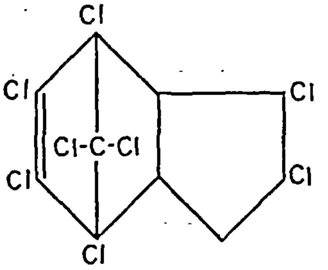
John L. Dadey, M.D.
and
A. G. Kammer, M.D., Pittsburgh

Chlordane is a recently developed insecticide with the empiric formula $C_{10}H_6Cl_8$. This chlorinated hydrocarbon is said to be 1,2,4,5,6,7,8,8-octachloro 2,3,3a,4,7,7a-hexahydro 4,7-methanoindene, with the structural formula shown in figure 1.

The commercially available technical product is not a pure substance, but contains in addition to chlordane some five or six closely related compounds whose respective proportions may vary.[1] The formulations of technical chlordane include oil solutions, emulsions, dusts, and wettable powders. These find extensive use in the eradication of such household pests as flies, cockroaches, fleas, and mosquitoes as well as agricultural crop enemies such as grasshoppers and certain beetles. Because of the widespread domestic, industrial, and agricultural distribution of the various preparations of chlordane, cases of accidental poisoning may be expected from time to time. These should be reported in order to alert physicians to the early recognition and proper treatment of chlordane intoxication.

The toxic action of chlordane on laboratory animals has been rather extensively studied. Stohlman, Thorp, and Smith[2] determined the LD_{50} of chlordane administered orally as a single dose in olive oil to be in the range of 200 to 250 mg. per kilogram of body weight for rats and 300 mg. per kilogram for rabbits. The rats given fatal doses usually exhibited dyspnea, labored respirations, tremors, convulsions, and coma before death, and the changes in these animals most frequently noted post mortem were ileitis, mottled liver, and pulmonary congestion, which was usually associated with focal hemorrhages. Stohlman and Smith[3] found that rabbits acutely poisoned with chlordane exhibited generalized tremors, opisthotonos, and tonic and clonic convulsions, and that these changes were diminished or abolished by appropriate doses of barbiturates. The LD_{50} of chlordane administered intravenously was increased in amounts approximating 20 to 60 mg. per kilogram in rabbits treated with these drugs.

In chronic toxicity studies reported by Stohlman and his associates,[2] rats that were given a semisynthetic diet containing 0.1% of chlordane usually died in about 10 days, and impaired liver function was demonstrated in rats that were similarly given smaller doses. The principal necropsy findings in rabbits in which chronic intoxication was produced through inclusion of chlordane in the diet were fatty and hyaline degeneration of the liver cells, degenerative changes in the proximal convoluted renal tubules, a low grade enteritis, and exudates throughout the pulmonary passages and alveoli. Albuminuria was a common development in nearly all of such rabbits. Lehman[4] found that dogs are more susceptible to chronic poisoning by chlordane than are rats. Ingle and others[5] have expressed the belief that chlordane is stored in the body in adipose tissue. Ingle reported that a group of rats that had been maintained for 80 weeks at dietary levels of 150 ppm of chlordane did not exhibit the hyperexcitability and tremors that are considered to be the earliest manifestations of chlordane intoxication in rats. When food was withheld from four of these rats, they all died after 36 hours, exhibiting the changes characteristic of poisoning by chlordane. The inference was drawn that lethal doses were released from storage when fats were mobilized in response to starvation.



Chlordane

Fig. 1.—Structural formula of chlordane.

The hazard of skin absorption of chlordane preparations was the subject of studies by Ambrose and his associates.[6] These workers applied chlordane in cottonseed oil and in ethyl alcohol to the depilated skin of albino rats. The administration of chlordane in cottonseed oil by this method in amounts of 50 mg. per day for three days, or for a total dose of 217 mg. per kilogram, caused fatalities among all rats tested. Chlordane in alcohol, however, when similarly administered in like doses produced no evidence of intoxication. These findings suggest that in some, but not all, preparations of chlordane the hazard of skin absorption may be equal to that of ingestion.

Stohlman and co-workers investigated the relationship between the dose of chlordane administered to rabbits and the quantity of organic chlorine which subsequently appeared in the urine. The data of their report have been used by us for the construction of a curve (fig. 2) that

shows this relationship for the first 24 hour period following chlordane administration.

The effect on humans of continuous exposures to small amounts of chlordane was the subject of a report by Princi and Spurbeck,[7] who presented a clinical study of 34 workers engaged from one to three years in the manufacture and formulation of chlordane and the chemically related compounds aldrin and dieldrin. The concentrations of mixtures of these three substances in the atmosphere of the work environment were estimated on the basis of the chlorine content of the air to be somewhat in excess of 5 mg. per cubic meter. The authors assumed that there was some absorption of these compounds through the skin in addition to the obvious pulmonary route. Thorough clinical examinations of the workers thus continuously exposed did not show any relevant central nervous system, hepatic, hemopoietic, or renal changes. Although it is impossible from the data in the published paper to calculate an approximate dose that these workers might have absorbed, the study does establish that there is some quantity of chlordane that may be taken into the body daily for at least three years without discernible ill-effect. A reasonably precise definition of this quantity needs to be established by further studies.

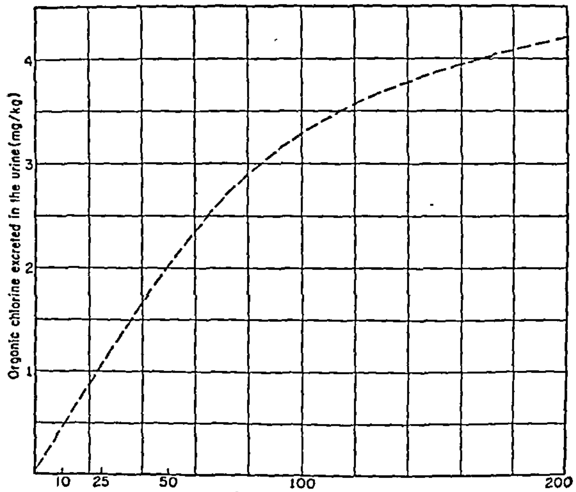

Fig. 2.—Urinary excretion of organic chlorine during the first 24 hours following administration of chlordane as a function of the dose administered to rabbits.

The published literature available to the authors contains records of two previous cases of chlordane intoxication. One of these, described by Lemmon and Pierce,[8] has been questioned as an authentic case. It occurred in a 33-year-old housewife who was exposed for an unknown number of hours in a closed room to the vapors of a 1 or 2% solution of chlordane that had previously been applied to the room surfaces for insecticidal purposes. The patient was hospitalized four days later because of nausea, vomiting, and a cough productive of whitish sputum. There was a history of alcoholism before and during the chlordane exposure. The pertinent positive findings were an enlarged liver, and abnormal results of cephalin flocculation and sulfobromophthalein (Bromsulphalein) tests. A suspicion of hepatic cirrhosis would seem to be reasonable in this case. Heyroth,[9] in a communication discussing this report, points out that the absence of any mention of the expected neurological manifestations of chlordane poisoning is good reason for doubting the assumption that chlordane was the cause of illness in this patient.

Lensky and Evans [10] reported a case of a 15-month-old baby who accidentally drank a small amount of chlordane suspension. The amount taken by this child weighing 9 kg. was believed to be not more than a mouthful (less than 100 mg.) of the suspension. Three hours after ingestion there developed a generalized tremor followed by convulsions. Risus sardonicus, opisthotonus, bilateral ankle clonus, and generally hyperactive reflexes were present. The convulsions were controlled by the use of sodium amobarbital. During the next few days only moderate ataxia and irritability remained, and these progressively diminished and disappeared after three weeks. This case strongly suggests that treatment should be immediately directed toward the removal of chlordane from the body even when the amount ingested is apparently trivial.

REPORT OF A CASE

At 7:30 a. m. on March 2, 1953 (five hours before hospital admission), an 18-year-old college girl swallowed a teaspoonful of a commercial insecticide containing 40% agricultural grade chlordane (24% chlordane and 16% related compounds), 10% oil of pine, 10% polyethylene glycol, and 40% of petroleum distillate. The patient had mistaken this preparation for camphorated opium tincture (paregoric), which she customarily took for dysmenorrhea. The mistake was discovered at once. She ate some bread and milk for its possible value as an antidote, and went to school. At 9 o'clock, one and one-half hours later, she became nauseated and vomited; at 10:30 o'clock she experienced diplopia, blurring of vision, and twitching of the extremities. About noon, while lying down at the student infirmary, she had a generalized convulsion that is said to have lasted "a few minutes," following which arrangements were made for her admission to Woman's Hospital of Pittsburgh. En route to the hospital, four and one-half hours after she had swallowed the chlordane, she vomited a second time. The vomitus was said to have contained the bread and milk eaten earlier and to have had an odor suggestive of the chlordane solution. There was no history of any previous convulsive seizure, and the systemic review was otherwise noncontributory

The physical examination revealed a normally developed, slender, white girl, weighing about 50 kg., who was apparently comfortable and able to provide the historical details save for those of the convulsive seizure, which were furnished by her sister. There was a swollen area of contusion on the right frontal region; the tongue was lacerated and ecchymotic; and there was tenderness to palpation at the costovertebral angles. The general physical and neurological examinations otherwise revealed no abnormality, save that the patient was menstruating. The admission complete blood count showed normal values, and the urinanalysis revealed the presence of albumin and cells, which were considered due to menstrual discharge. Since there was at this time no satisfactory way of computing the dose of chlordane absorbed, certain blood chemistry determinations were made for their possible value as base lines on which to make future judgments relative to hepatic and renal functions. The blood levels of the following substances were found to be normal: nonprotein nitrogen, chlorides, carbon dioxide, sodium, potassium, calcium, total proteins, albumin, globulin, and cholesterol. Analysis of a pooled specimen of urine collected during the first 24 hours of hospitalization revealed 1 mg. of organic chlorine per 100 ml., the total amount excreted during the period being 22 mg.

[8] Lemmon, G. B., Jr., and Pierce, W. F.: Intoxication Due to Chlordane, J. A. M. A. 149: 1314 (Aug. 2) 1952.

[9] Heyroth, F. F.: Chlordane Poisoning, J. A. M. A. 150: 715 (Oct. 18) 1952.

[10] Lensky, P., and Evans, H. L.: Human Poisoning by Chlordane, J. A. M. A. 149: 1394 (Aug. 9) 1952.

After her stomach was emptied and lavaged, the patient was not permitted to take anything by mouth for 24 hours. She was given fluids intravenously to prevent superposition of dehydration and electrolyte depletion upon the action of a possible nephrotoxic agent and possibly to enhance the renal excretion of this toxin. Accordingly, she received 2,000 ml. of 10% glucose in water and 1,000 ml. of 10% glucose in saline with water-soluble vitamins intravenously during the ensuing 20 hours. During this time her urinary output was 2,230 ml. Since there was no further convulsion or nausea, a soft diet was started on the day following admission to the hospital. The costovertebral angle tenderness was no longer present after the third day, and the remainder of her hospital course was uneventful. The blood counts and urinalysis findings continued to be normal; the blood chloride level, and serum levels of sodium, potassium, and phosphate were redetermined and found normal, as was thymol turbidity; and the cephalin flocculation test was negative. The patient was discharged from the hospital on March 7, 1953, five days after admission. After her discharge she continued to do well. An electroencephalogram, performed on April 28, was normal, and visual field examinations on May 5 revealed no abnormality.

COMMENT

As with other chemical poisons, the events to be expected in a case of acute poisoning by chlordane depend upon the dose absorbed. On the advice of Lehman,[1] chlordane and its closely related compounds in a solution of technical chlordane are to be considered together in the estimation of the dose administered. The amount of chlordane ingested in the present cases is calculated on this basis to have been 40% of 4 gm., or 1.6 gm. (32 mg. per kilogram). It should be assumed that the amount actually absorbed was less than this, but how much less cannot be definitely established. In any case, the amount absorbed was sufficient to cause transient minor central nervous system changes followed by convulsions, from all of which the patient recovered spontaneously. In a case of poisoning in an infant previously reported,[10] it was necessary to administer a barbiturate for the control of convulsions. These two cases suggest that acute poisoning in man by ingestion of a single dose of chlordane results in a series of central nervous system changes that culminate in convulsions. It is likely that a dose insufficient to produce central nervous system changes is also insufficient to produce significant changes in other organ systems. On the basis of results of acute toxicity studies in animals, it may be predicted that doses large enough to produce severe convulsions will also cause hepatic necrosis. Since the administration of chlordane over prolonged periods has produced damage of the renal convoluted tubules, this change needs to be borne in mind as a possibility in cases of poisoning among humans.

It may prove possible to estimate with satisfactory accuracy the dose of chlordane absorbed from the level of organically bound chlorine in the urine. As demonstrated by the curve in figure 2, which is based upon Stohlman's data, there is a reasonably good correlation of this type in rabbits administered single doses of chlordane. If a like correlation exists for humans, then it is possible to make an estimation of the amount of chlordane retained in the present case. The 24 hour urinary excretion of organic chlorine was 22 mg. which in this 50 kg. patient was 0.44 mg. per kilogram. From the curve in figure 2 this excretory level is representative of a retained dose of 10 mg. per kilogram. The total dose retained therefore would be 10 mg. times 50, or 500 mg. of chlordane, a value that seems reasonable in consideration of the vomiting that occurred one and one-half and again four and one-half hours following ingestion of 1.6 gm. of chlordane dissolved in oil and petroleum distillate. Because of the limitations of translating animal data to humans, no estimation is offered of a probably fatal single dose of chlordane for humans, or of the relationship of the retained dose in the presently reported case to this value. The data in the present case suggest that a dose of chlordane that results in an urinary excretory value of about 0.5 mg. of organic chlorine per kilogram during the ensuing 24 hours is sufficient to cause only transitory central nervous system changes from which the patient may be expected to recover spontaneously and completely. Because of the obvious advantage of knowing the absorbed dose at the earliest possible time, it is hoped that the relationship between dose and the urinary level of organic chlorine will be more thoroughly studied in any future cases. The practical application of routinely determined urinary organic chlorine levels as an industrial hygiene control measure among workers who are regularly in contact with chlordane is strongly suggested.

Barbiturates, especially those that are detoxified in extrahepatic tissues, may be considered to have established value in the convulsive state produced by chlordane. It is possible at this time only to assume that the usual therapeutic measures effective for hepatic necrosis will be useful in the more advanced stages of poisoning. The occurrence of lower nephron nephrosis following a single dose of chlordane is not predictable from experimental data or case reports now at hand, but this serious change should always be borne in mind. The present case, as well as one previously reported, suggests that the ingestion of 10 mg. of chlordane per kilogram of body weight, and perhaps less, is an indication for gastric lavage at the earliest feasible time.

SUMMARY

A case of human intoxication with chlordane is presented in which the dose ingested was approximately 30 mg. per kilogram of body weight and the amount retained after vomiting is estimated to be 10 mg. per kilogram of body weight. Experiences with chlordane intoxication in laboratory animals and one other human case are discussed. Central nervous system changes manifested by convulsions, with or without coma, are the outstanding characteristics of acute chlordane intoxication. Measures for handling future cases are discussed and include early evacuation of stomach contents, anticonvulsive agents, and, in severe cases, such measures as may be necessary to counteract liver damage as well as possible renal tubular changes.

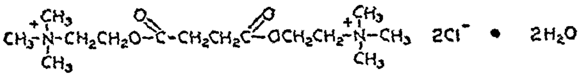
Succinylcholine Chloride.—Anectine Chloride (Burroughs Wellcome).—Quelicin Chloride (Abbott).—$C_{14}H_{30}Cl_2N_2O_4.2H_2O$.—M.W. 397.34.—Choline succinate dichloride dihydrate.—The structural formula of succinylcholine chloride may be represented as follows:



Actions and Uses.—Succinylcholine chloride is a myoneural blocking agent that produces a skeletal muscle relaxant effect somewhat resembling that of curare and curare-like compounds. It likewise produces muscle relaxation as an adjunct to anesthesia during surgical procedures and in conjunction with electroshock therapy. Succinylcholine chloride is a shorter-acting drug than tubocurarine chloride and, therefore, is particularly suited for endotracheal intubation, endoscopy, and other short, manipulative procedures. In contrast to tubocurarine chloride, succinylcholine chloride is not antagonized by anticholinesterases; and the injection of such drugs as physostigmine, neostigmine, procaine, or edrophonium prolongs its action. This suggests that the short action of the drug is caused by relatively rapid hydrolysis of the ester linkage by enzyme action, such as that of cholinesterases. Presumably, the drug is rapidly hydrolyzed into nontoxic choline and succinic acid and is not dependent on the liver or kidneys for detoxication or excretion.

Tachyphylaxis or cumulative action is not ordinarily encountered, but like other myoneural blocking agents, succinylcholine chloride in extremely high doses may produce respiratory depression, persisting after the diaphragmatic response to phrenic nerve stimulation has returned. Facilities for controlled, involuntary respiration and for the administration of oxygen to insure adequate respiratory exchange should be available for combating respiratory paralysis. *Neostigmine or other anticholinesterases and edrophonium are contraindicated as antidotes for succinylcholine chloride.* Succinylcholine chloride should be used with caution in patients with severe liver disease, severe anemia, and malnutrition or in those suffering from polyphosphate insecticide poisoning who may have decreased plasma-cholinesterase activity that might intensify and prolong the action of the drug. In such patients, artificial respiration and oxygen therapy may be supplemented by the administration of plasma or whole blood to restore cholinesterase activity.

Because succinylcholine chloride is rapidly hydrolyzed by alkaline solutions, it loses its potency rapidly when mixed with thiopental sodium. For this reason, separate injection is preferable.

Succinylcholine chloride is quite stable when stored under refrigeration. When exposed to room temperature for a long time, its potency gradually decreases; however, biological assay has shown that solutions may be kept as long as three months at room temperature without significant loss of potency.

Dosage.—Succinylcholine chloride is administered in solution by the intravenous route, either as a single intermittent injection or as a continuous drip infusion.

For short procedures, the suggested adult dose is 20 mg. for a single injection; the optimum dose ranges from 10 to 30 mg. Within this range each such dose usually produces relaxation in about one minute. Maximum muscular relaxation may persist for about two minutes, followed by rapid recovery within the next few minutes. Since the maximum safe dosage of the drug has not been determined, and since the response obtained may vary in different patients, careful observation of respiratory exchange is essential to avoid paralytic apnea.

For prolonged procedures, sustained relaxation may be obtained with a continuous intravenous drip infusion at a dosage rate of 0.5 mg. to 10 mg. (average 2.5 mg.) per minute for adults. The solution of the drug to be infused may be prepared by dilution of 500 mg. of succinylcholine chloride in 250 or 500 cc. of sterile isotonic sodium chloride solution or 5% dextrose solution, thus providing a 0.1% (1 mg. per cubic centimeter) or a 0.2% (2 mg. per cubic centimeter) solution, respectively. The degree of relaxation can be altered in approximately 30 seconds by regulating the rate of the drip infusion. Careful supervision of the infusion and the control of respiration are absolutely essential to avoid hypoxia.

Tests and Standards.—

Physical Properties: Succinylcholine chloride is a white, odorless, slightly bitter powder, m.p. of the hydrate, 156-163°. It is very soluble in water, very slightly soluble in benzene and chloroform, and practically insoluble in ether. The amount which dissolves in alcohol to form 100 ml. of solution is 0.42 gm. Aqueous solutions of succinylcholine chloride are relatively unstable at room temperature. The pH of a 2% solution is 3.0-4.5.

Identity Tests: Dissolve about 50 mg. of succinylcholine chloride in 10 ml. of water and divide the solution into two portions. To one portion add 2 drops of nitric acid and 1 ml. of silver nitrate T.S.: a white precipitate forms, which is insoluble in diluted nitric acid, but soluble in diluted ammonia solution *(presence of chloride).* To the second portion add 10 ml. of saturated picric acid and 2 drops of diluted sulfuric acid. Place the mixture in a refrigerator for 1 hour. Filter the mixture, wash the precipitate thoroughly with ether, and dry it at 105° for 15 min. *(Caution! May be explosive. Use safety glass shield.):* the crystals melt at 155-159°.

Purity Tests: Dissolve 0.1 gm. of succinylcholine chloride in enough water to make 25 ml. of solution, add 1 ml. of barium chloride T.S., shake, and allow the mixture to stand for 1 min.: the turbidity does not exceed that of 0.2 ml. of 0.02 *N* sulfuric acid diluted to 25 ml. and treated in the same manner *(presence of sulfate).*

Dry about 1 gm. of succinylcholine chloride, accurately weighed, in a vacuum at 105° for 5 hours: the loss in weight does not exceed 10.0%.

Char about 1 gm. of succinylcholine chloride, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until evolution of sulfur trioxide ceases; ignite, cool, and weigh: the residue does not exceed 0.1%.

Assay: (Succinylcholine Chloride) Transfer to a 100 ml. beaker an amount of powder equivalent to about 0.2 gm. of anhydrous succinylcholine chloride, accurately weighed, and dissolve it in 50 ml. of recently boiled and cooled water. Potentiometrically adjust the pH to 7.5 with 0.01 *N* sodium hydroxide and transfer the solution to a 300 ml. flask. Add exactly 20 ml. of 0.1 *N* sodium hydroxide, reflux for 40 min., and cool. Transfer the solution to a 250 ml. beaker and potentiometrically titrate the excess alkali with 0.1 *N* hydrochloric acid to a pH of 7.5. Run a blank titration using 50 ml. of recently boiled and cooled water. Each milliliter of 0.1 *N* sodium hydroxide consumed is equivalent to 0.01807 gm. of anhydrous succinylcholine chloride. The amount of anhydrous succinylcholine chloride is not less than 98.5 nor more than 101.5%.

(Chloride) Transfer to a 250 ml. Erlenmeyer flask about 0.3 gm. of anhydrous succinylcholine chloride, accurately weighed. Add 100 ml. of water and 1 ml. of potassium chromate T.S. Titrate with 0.05 *N* silver nitrate. Each milliliter of 0.05 *N* silver nitrate is equivalent to 0.001773 gm. of chloride and 0.009033 gm. of anhydrous succinylcholine chloride. The amount of chloride is not less than 19.2 nor more than 20.0%, equivalent to not less than 98.0 nor more than 102.0% of succinylcholine chloride.

Dosage Forms of Succinylcholine Chloride

SOLUTIONS. *Physical Properties:* The pH of the 2% and 5% solution is 3.0-4.5.

Identity Tests: The solution responds to the identity tests for the active ingredient in the monograph for succinylcholine chloride.

Assay: (Succinylcholine Chloride) Transfer to a 125 ml. separatory funnel an amount of solution, accurately measured, equivalent to about 0.2 gm. of anhydrous succinylcholine chloride. Add 40 ml. of recently boiled and cooled water, extract with five 25 ml. portions of ether, and combine the extracts in a 250 ml. separatory funnel. Wash the extracts with three 5 ml. portions of water. Discard the ether extracts and reextract the combined wash solutions with two 10 ml. portions of ether, adding the aqueous phase to the extracted aqueous solution. Proceed as directed in the assay for succinylcholine chloride in the monograph for succinylcholine chloride starting with, "Potentiometrically adjust the pH to 7.5 . . . ." Each milliliter of 0.1 *N* sodium hydroxide consumed is equivalent to 0.01807 gm. of anhydrous succinylcholine chloride. The amount of anhydrous succinylcholine chloride is not less than 92.5 nor more than 107.5% of the labeled amount calculated to the anhydrous basis.

Abbott Laboratories, North Chicago, Ill.

Solution Quelicin Chloride: 10 cc. vials. A solution containing 20 mg. of succinylcholine chloride in each cubic centimeter. Preserved with 0.18% methylparaben and 0.02% propylparaben.

Solution Quelicin Chloride: 10 cc. ampuls. A solution containing 50 mg. of succinylcholine chloride in each cubic centimeter.

Gold Leaf Pharmacal Company, Inc., New Rochelle, N. Y.

Tablets Mephenesin: 0.5 gm.

Methapyrilene Hydrochloride (See New and Nonofficial Remedies 1953, p. 9).

Chemo Puro Manufacturing Corporation, Long Island City, N. Y.

Powder Methapyrilene Hydrochloride: Bulk; for manufacturing use.

Neostigmine Bromide-U.S.P. (See New and Nonofficial Remedies 1953, p. 182).

Hoffmann-LaRoche, Inc., Nutley, N. J.

Ophthalmic Solution Prostigmin Bromide 5%: 7.5 cc. dropper bottles. A solution containing 50 mg. of neostigmine bromide in each cubic centimeter. Buffered with 1% boric acid. Preserved with 0.18% methylparaben and 0.02% propylparaben.

Neostigmine Methylsulfate-U.S.P. (See New and Nonofficial Remedies 1953, p. 182).

Lincoln Laboratories, Inc., Decatur, Ill.

Solution Neostigmine Methylsulfate 1:2000: 10 cc. vials. Preserved with 0.45% phenol.

Pentaerythritol Tetranitrate (See New and Nonofficial Remedies 1953, p. 244).

Chemo Puro Manufacturing Corporation, Long Island City, N. Y.

Powder Pentaerythritol Tetranitrate: Bulk; for manufacturing use. A mixture containing 75 mg. of pentaerythritol tetranitrate in each gram of powder.

Progesterone-U.S.P. (See New and Nonofficial Remedies 1953, p. 376).

Gold Leaf Pharmacal Company, Inc., New Rochelle, N. Y.

Solution Corlutone in Oil: 1 cc. ampuls and 10 cc. vials. A solution in sesame oil containing 10 and 25 mg. of progesterone in each cubic centimeter. The 10 cc. vials are preserved with 0.5% chlorobutanol.

Pyridoxine Hydrochloride-U.S.P. (See New and Nonofficial Remedies 1953, p. 493).

American Pharmaceutical Company, New York.

Tablets Pyridoxine Hydrochloride: 10 and 25 mg.

Pyrilamine Maleate (See New and Nonofficial Remedies 1953, p. 12).

The Columbus Pharmacal Company, Columbus, Ohio.

Tablets Pyramal Maleate: 50 mg.

Riboflavin-U.S.P. (See New and Nonofficial Remedies 1953, p. 496).

Hart Drug Corporation, Miami, Fla.

Tablets Riboflavin: 5 and 10 mg.

Sodium p-Aminosalicylate (See New and Nonofficial Remedies 1953, p. 91).

Chemo Puro Manufacturing Corporation, Long Island City, N. Y.

Powder Sodium Para-Aminosalicylate: Bulk; for manufacturing use.

Merck & Company, Inc., Rahway, N. J.

Powder Sodium Para-Aminosalicylate: 500 gm. bottles and 2.5, 11.35 and 45.4 kg. fiber drums; for manufacturing use.

Sodium Dehydrocholate (See New and Nonofficial Remedies 1953, p. 337).

Lincoln Laboratories, Inc., Decatur, Ill.

Solution Sodium Dehydrocholate: 10 cc. ampuls. A solution containing 0.2 gm. of sodium dehydrocholate in each cubic centimeter.

CHLOROPHYLL AND DEODORIZATION

There was published in THE JOURNAL[1] an editorial entitled "Chlorophyll as a Deodorant." This precipitated considerable correspondence, some of which came from those with interests in the commercial possibilities for preparations containing chlorophyllins. Some of the correspondents questioned some of the statements made in the editorial, some referred to articles published elsewhere that they believed offered convincing evidence of the value of chlorophyll or its derivatives as a deodorant. For several years there has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association a chlorophyllin-type preparation that is promoted only to the medical profession and with claims recognized by the Council. No other preparations stand accepted by the Council, and the evidence for the claimed usefulness of chlorophyll toothpastes, mouthwashes, chewing gum, tablets to be taken by mouth, and other similar concoctions seems to be wanting or at least open to dispute. As THE JOURNAL editorial pointed out, "It seems apparent that no final conclusion can be reached about the deodorizing effects of chlorophyll derivatives until the composition of the various preparations is more exactly delineated, the fate of ingested chlorophylls in the body is determined, and more objective testing has been done."

Elsewhere in this issue (page 745) is reproduced some of the correspondence received in the editorial office. This had barely been accepted by the Editor when there was published in a local newspaper (Sept. 30) an Associated Press release on a panel discussion at the annual meeting of the American Dental Association. According to the release, one of the participants in the panel said "claims that toothpastes containing chlorophyll can give a deodorizing effect for several hours should be viewed with suspicion." So far there appears to have been no official denial of such a statement by organized dentistry, and it is presumed, therefore, that the incorporation of chlorophyll derivatives in toothpastes is open to suspicion as far as claims are concerned. Other information reaching THE JOURNAL office indicates validity of THE JOURNAL'S earlier assertion that there is need for conclusive evidence before many of the claims offered for this type of preparation and others sold widely to the public can be accepted without any suspicion.

SURGICAL SURVIVAL OF THE YOUNG AND THE AGED

Although operations performed on elderly patients under most circumstances are more hazardous than when done on young patients, Cole[1] points out that it is not generally realized that, if concurrent and complicating diseases are eliminated, aged patients will tolerate operative procedures of moderate magnitude almost as well as the young. Few will dispute the statement that the reserve of certain body functions and organs decreases with the passing of time. There is, for instance, reliable evidence to demonstrate that the elasticity of arteries and arterioles decreases with age; consequently, elderly persons are more susceptible to vascular shock than young persons. Similarly, arteriosclerotic changes in the vascular supply of the kidney make the elderly patient especially vulnerable to renal dysfunction, while degenerative vascular changes probably explain why older persons tolerate heat and cold so poorly. Moreover, elderly patients are more susceptible than the young to anoxia and to infections. As a result of these changes, it is to be expected that older patients will have a lower physiological reserve to combat major operations.

In order to determine the mortality rate of patients less than 60 years of age as compared to patients over 60, Cole made a survey of 3,656 major operations that were performed by members of the general surgical service at the Illinois Research Hospital from 1948 to 1952 inclusive. He limited the study to patients subjected to various types of abdominal, thoracic, vascular, plastic, urologic, breast, extremity, and neck surgery. Radical excision of the breast, thyroidectomy, and all types of herniorrhaphy were considered major operations. The majority of abdominal and thoracic procedures consisted of operations for inoperable carcinoma, with most colostomies, gastrostomies, and radical oral and neck operations performed for this disease. In addition, such procedures as pulmonary lobectomies, suprapubic and retropubic prostatectomies, enteroenterostomies, and pancreatectomy came within the scope of the survey.

Cole concluded that there is an accumulation of evidence to demonstrate that if the operative load lies within certain limits and if elderly patients are rendered free from concurrent disease, the mortality rate of the aged in major operations of slight magnitude is almost equal to that found in younger patients, provided, of course, all decrements and insufficiencies are met before operation and excellent postoperative care is instituted. Contrariwise, in the case of operations of greater magnitude, the mortality rate to be expected in the older group may be two to four times higher than in the younger group. A survey of reports appearing in the medical literature indicates that the mortality rate encountered as the result of emergency operations performed on the aged is substantially higher than in elective surgical procedures. The Illinois Research Hospital study also demonstrated that the mortality rate following radical excision of the breast, cholecystectomy, gastrectomy, herniorrhaphy, and thyroidectomy was no higher in patients over 60 years of age than in patients under 60. The mortality rate in 2,577 operations performed on patients under 60 at this institution was 2.07% as compared to 5.1% in 1,099 patients over 60 years of age.

DIAGNOSIS OF MITRAL REGURGITATION

Estimation of the degree of mitral insufficiency in candidates for mitral commissurotomy is of considerable importance. While mild to moderate regurgitation need not significantly effect the outcome, severe regurgitation is a contraindication to the procedure.[1] With a view to evaluating criteria commonly used for diagnosing mitral regurgitation, Abelmann, Ellis, and Harken [2] have correlated the clinical findings in candidates for valvuloplasty with pathological anatomic observations made at surgery or at autopsy. Sixty-four persons in all were studied. In 62 of these some degree of mitral stenosis was found at operation. Twenty-seven were found at operation to have some degree of mitral regurgitation, which was graded according to the size and force of the regurgitant jet as felt by the surgeon's finger. One was found to have pure mitral insufficiency at operation, and in one the diagnosis of pure mitral insufficiency suspected during life was confirmed at death, which occurred before surgical correction was attempted. The following criteria were examined: the apical systolic murmur, the symptom of easy fatigability, enlargement of the left ventricle, absence of electrocardiographic pattern of right ventricular enlargement or right bundle branch block, marked enlargement of the left auricle, systolic expansion of the left auricle as assessed by fluoroscopy, the auricular esophagogram, the auricular border electrokymogram, and the phonocardiogram.

It was found that the most valid criteria for the diagnosis of marked mitral regurgitation were the presence of a loud apical systolic murmur, marked left auricular enlargement, left ventricular enlargement, and systolic expansion of the left auricle by fluoroscopy. Thus, of 14 patients with apical murmurs of grade 3 or louder, 6 showed severe regurgitation at operation, 4 showed mild to moderate regurgitation, and 4 showed no regurgitation. On the other hand, of 23 patients without systolic murmurs, there was no regurgitation in 15, it was questionable in 7, and it was moderate in 1. Again, of nine patients with marked regurgitation, six had markedly enlarged left auricles and three had moderate enlargement only. Contrariwise, of 45 patients with slight or moderate enlargement, 29 had pure stenosis, 13 had questionable to moderate regurgitation, and only 3 had marked regurgitation. Of 15 patients showing definite left ventricular enlargement by either electrocardiogram or roentgen examination, all but 2 showed mitral regurgitation; however, failure to demonstrate left ventricular enlargement does not rule out mitral regurgitation, since 8 patients with moderate to severe regurgitation did not show definite evidence of left ventricular enlargement.

In regard to systolic expansion of the left auricle as observed fluoroscopically, of 48 patients who were subjected to fluoroscopic studies, 33 showed definite expansion of the left auricle. Seven of 8 patients with marked regurgitation fell in this category while in the eighth patient expansion was questionable. However, 7 of 17 patients without demonstrable regurgitation also showed systolic expansion.

In 47 patients on whom all four of the above tests were run, it was found that any two of the four criteria were met by 5 of 7 patients with marked regurgitation, by 12 of 19 patients with mild to moderate regurgitation, by 1 of 4 patients with questionable regurgitation and by only 1 of 17 patients with pure stenosis.

In regard to the other criteria, fatigability overshadowing dyspnea was observed in nine patients, only four of whom show regurgitation to a moderate to marked degree. While it is claimed that the absence of electrocardiographic evidence and right ventricular hypertrophy in patients with mitral disease suggests the presence of both stenosis and regurgitation, Abelmann and his associates report that 15 of the 32 patients with no evidence of bundle branch block or right ventricular hypertrophy by electrocardiogram showed no evidences of mitral regurgitation at valvuloplasty while 11 showed only questionable or mild insufficiency, which indicates that such patterns are not restricted to patients with both stenosis and regurgitation. Studies with auricular esophagograms confirmed the existence of an esophageal auricular pressure pulse characteristic for mitral regurgitation but proved too sensitive a method to quantitate mitral regurgitation. In fact, the presence of this pattern in many patients in whom no regurgitant jet was felt by the surgeon tends to confirm the viewpoint that mitral stenosis is almost invariably accompanied by some degree of regurgitation. Abelmann and co-workers also found left auricular border electrokymography disappointing, patterns reportedly characteristic of mitral regurgitation being found in all patients with mitral disease and in many patients without heart disease, while phonocardiogram results appeared to be too inconstant to be of any diagnostic value.

The authors conclude from these studies that no single criterion is adequate for the preoperative diagnosis of severe mitral regurgitation in patients with mitral stenosis. They feel, however, that consideration of all clinical findings usually permits assessment of the individual patient. Thus the presence of a systolic murmur of grade 2 or less, a left auricle moderately enlarged in posterior direction only, evidence of right ventricular enlargement by roentgenogram or electrocardiogram without evidence of left ventricular enlargement, and the finding of definite but slight systolic posterior expansion of the left auricle by fluoroscopy, kymogram, or esophagogram suggest that mitral insufficiency of a degree to contraindicate cardiac surgery is not present. On the other hand, definite evidence of left ventricular enlargement, associated with other presumptive signs of regurgitation, such as a loud systolic murmur, marked left auricular enlargement with systolic expansion, and fatigability rather than dyspnea are suggestive of mitral insufficiency sufficiently advanced to render exploratory cardiotomy inadvisable.

ORGANIZATION SECTION

STATEMENT BY EDWARD J. McCORMICK ON MEDICAL RESEARCH AND PROGRESS BEFORE HOUSE COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE

I am Dr. Edward J. McCormick of Toledo, Ohio, where I am engaged in the active practice of medicine. I am President and a member of the Board of Trustees of the American Medical Association. I am appearing here today as a representative of that Association to discuss our interest and activities in the field of medical research and to offer to your Committee our complete cooperation and the use of our facilities in connection with your current inquiry.

It is our understanding that this hearing has been initiated by your Committee for the purpose of studying the causes, methods of control and the extent of medical progress in connection with several specific diseases. It is apparent from the list of organizations which are scheduled to testify that complete and authentic information in this regard will be available to you. For that reason it has been decided, with the approval of Mr. John H. Teeter, Special Consultant to your Committee, not to present a separate statement with respect to each of the diseases to be covered. In addition to my statement, a representative from the Washington office of the American Medical Association will be in attendance for the entire hearing. If there are any questions which the Committee may want to direct to the Association, our representative will either supply the answer or refer the request to our headquarters in Chicago for necessary action. Finally, at the conclusion of the initial phase of the hearings we will be happy to submit a written statement or send another witness to discuss in detail any controversial issues which may arise. It is our belief that this approach will conserve the time of the Committee and prevent duplications in the presentation of basic material.

The one exception to this plan will be made tomorrow when the subject of cancer is to be discussed. In view of the extensive work of the American Medical Association in this field, I have asked Dr. Paul Wermer, the Secretary of our Committee on Research, to outline for you the activities of the Association concerning cancer diagnosis, treatment and research.

With these introductory remarks I should like to proceed to a brief statement concerning the composition, purposes and program of our Association.

The American Medical Association was founded on May 5, 1847, when 250 delegates representing more than 40 medical societies and 28 colleges, embracing medical institutions in 22 states and in the District of Columbia, met in Philadelphia, Pennsylvania. It has since grown from an organization of a few thousand to a membership of approximately 140,000, with 53 constituent state and territorial medical associations and about 2,000 component county and district medical societies.

The American Medical Association is a physician's organization existing to serve the medical profession and the general public. Since its inception it has campaigned to elevate the standards of medical education, licensure and public health; to maintain its high ethical standards; to oppose charlatanism; to promote clinical and scientific investigation, and to make available a better quality of medical service.

Although the American Medical Association acts collectively for physicians in the socio-economic field of medicine, which includes ethics, laws and legislation, medical service, economic research, rural health and health education, primary emphasis is placed on its scientific activities.

During the year 1952 over 80% of our expenditure of approximately $10,000,000 was devoted to this work. These activities are conducted largely by the Council on Medical Education and Hospitals, the Council on Scientific Assembly, the Bureau of Exhibits, the Committee on Mental Health, the Council on Pharmacy and Chemistry, Council on Physical Medicine and Rehabilitation, Council on Foods and Nutrition, Committee on Cosmetics, Committee on Research, Bureau of Investigation, and the Chemical Laboratory and Microbiologic Laboratory.

It would take considerable time for me to discuss in any detail the purposes and programs of these units of our Association. Suffice it to say that all of their work is extremely important in advancing the science of medicine. The outstanding reputation of the members of these Councils and Committees for specialized scientific knowledge and integrity is well recognized. These men serve without remuneration and render unbiased decisions based on careful considerations of all available scientific evidence and expert opinion.

Through The Journal of the American Medical Association, published weekly, and the nine monthly scientific journals, as well as several special books, the Association aids physicians in their search for new medical knowledge. These publications assist the medical profession in keeping abreast of medical developments, serve as an important means of postgraduate medical education and carry information on organization activities, as well as on government services.

In addition to such inter-Association groups, the American Medical Association has for many years engaged in a variety of cooperative undertakings with allied health agencies as well as with the state and federal governments. The operations of three such joint agencies which are currently in existence may be of interest to your Committee.

The National Research Council.—This agency was established in its present form in 1916 by the National Academy of Sciences and organized with the cooperation of the National Scientific and Technical Societies of the United States. Its purpose is to promote research in the natural sciences and in their application to medicine and other useful arts with the object of increasing knowledge, strengthening the national defense and contributing in other ways to the public welfare. To this end the Council furnishes professional and research advice to governmental and other organizations and administers such funds as may be entrusted to it.

The American Medical Association maintains liaison with the National Research Council through representation on the Division of Medical Sciences and the Food and Nutrition Board. In this capacity we are able to assist and cooperate in the effective prosecution of the Council's work.

The Commission on Chronic Illness.—This Commission was founded in 1949 as a non-profit organization by the American Medical Association, the American Hospital Association, the American Public Health Association and the American Public Welfare Association. At the present time 12 national organizations contribute financially and professionally to the program of the Commission.

Studies of the Commission include those to determine the prevalence and incidence of the major chronic diseases and how many and what services are needed; studies to determine effective means of prevention, rehabilitation and care; fact finding projects to learn what services and facilities are now available and what kinds of planning are going on.

Briefly, it can be stated that the goals of the Commission are to define the problems arising from chronic illness in all age groups; pave the way for dynamic programs to prevent chronic illness, minimize its disabling effects, restore its victims to a socially useful and economically productive place in the community; clarify the interrelationships of the many professional groups and agencies working in the field; coordinate the separate programs designed to meet more effectively the needs common to all the chronically ill; stimulate in every locality a well-rounded plan for the prevention and control of chronic disease and for the care and rehabilitation of the chronically ill; and modify society's attitude that chronic illness is hopeless.

Committee on Relations Between Medicine and Allied Health Agencies.—In June 1952 the House of Delegates of the American Medical Association authorized this Committee for the purpose of establishing better coordination and understanding between voluntary health agencies. It was also the intention of the House of Delegates to encourage the development of case finding methods, in the office of physicians, which would be more effective than the mass surveys employed by most public and private agencies.

Now, a word about medical programs in general. The advances of medical science since the beginning of the twentieth century offer convincing evidence of what can be done when competent researchers have an opportunity to work with freedom, facilities and funds. A review of the medical discoveries since the turn of the century would require volumes. Drugs and operations, for example, alone could provide endless material for discussion of the onward march of medical research. Insulin, vitamins, sulfonamides, penicillin and other antibiotics are only a few of the outstanding discoveries in the drug field. Isotopes and betatrons have become part of the medical language. Even entirely new approaches to illness have been discovered, as a result of which, the full possibilities of formerly practically unknown subjects such as physical medicine and rehabilitation are being explored with a thoroughness that offers much promise for the future. Truly, the past fifty years have been remarkable for those who devote their lives to the prevention of illness and the treatment of the sick.

The decline in the general mortality rate from 17.2 deaths per 1,000 population in 1900 to only 9.6 in 1950 underscores the health progress during this period. While the population has doubled, the number of persons over 65 years of age has quadrupled in this period and a significant gain in life expectancy, even in late middle age, has resulted from the mortality reduction. Life expectancy at birth in 1900 was estimated at 47.3 years; in 1949 it was 67.6 years.

Major mortality gains have resulted from preventive medicine and the development of specific cures. Preventive medicine has been successful in eliminating, in a large measure, the spread of disease. Medical research has developed many effective methods of immunization and disease prevention; these have been widely used by public health agencies and sanitary engineers under the capable guidance and direction of the medical profession.

In conclusion, I should like to say that the American Medical Association will continue to support all programs for the good of the health of the public, as we have done over the years. We shall fight, however, with all of our strength, matters that are not in the public interest. Our Association has, throughout its history, been a champion of sound progress in medicine. It has had to fight many battles against quackery, improper governmental interference and against slipshod medical training and practice. We have found that an organization cannot be strong and fearless in defending its principles without creating bitter enemies and staunch supporters. We have both today.

This concludes my formal statement. I want to thank the Committee for allowing our Association an opportunity to participate in these important hearings. I shall be happy to answer to the best of my ability any questions which members of the Committee may have.

STATEMENT BY PAUL WERMER ON CANCER DIAGNOSIS, TREATMENT, AND RESEARCH BEFORE HOUSE COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE

I am Dr. Paul Wermer of Chicago, Illinois. For six years I was a practicing physician in New York City. Thereafter I served for five years in the United States Public Health Service, after which I spent four years in clinical research work in the pharmaceutical industry. Since 1949 I have been the Secretary of the Committee on Research of the Council on Pharmacy and Chemistry of the American Medical Association. I am appearing here today as a representative of that Association to outline our activities in the field of cancer diagnosis, treatment and research.

As Dr. Edward J. McCormick indicated in his statement yesterday, the American Medical Association includes in its membership physicians from all walks of professional life and is interested and engaged in a variety of activities. Thus, cancer, while absorbing, does not represent the Association's sole interest in the fight against diseases and death. In line with the schedule of the Committee, I will limit my remarks today to the field of cancer. I will also attempt to avoid repeating information dealing with the description of the disease, its causes and general research data which has been covered by other witnesses.

I should like however, to emphasize our realization of the extreme seriousness of this particular disease. Obviously, a malady which is in second place among the causes of death is a matter of pressing concern not only to organized medicine but to every member of the profession. To each physician, whether family advisor or specialist, every death resulting from cancer is a defeat for scientific medicine. Thus, all of us are vitally interested in ascertaining the solution to this problem. We believe that this answer must be found by further education and research. In this manner we hope to determine the causes, the earliest method of diagnosis, the best treatments and the best methods for early determination of a patient's response to treatment.

In the field of cancer diagnosis, treatement and research, the American Medical Association plays a prominent professional educational role. The Journal of the American Medical Association is prepared and distributed weekly to close to 150,000 practicing physicians. During the year ending Sept. 26, 1953, THE JOURNAL published 21 articles and clinical notes, 156 abstracts of articles appearing in domestic and foreign medical journals, and answered a number of inquiries from domestic and foreign correspondents on the subject of cancer. In addition, THE JOURNAL has commented editorially on cancer in six of the 52 issues represented in this survey.

In addition, the Association publishes nine special journals monthly, each of which has carried several articles on cancer in the special areas of interest.

At the Annual Meeting of the American Medical Association in New York City this past June, there were 31 scientific papers and 25 scientific exhibits on cancer. In addition, there were two nation-wide television programs and five motion pictures shown to the visiting physicians dealing with this disease. The meeting was visited by approximately 18,000 practicing physicians and over 5,000 students, interns and technicians.

By these educational devices (our publications and our meetings) the American Medical Association brings to the readers of its journals and to its membership, the latest advances in acceptable methods of therapy and diagnosis. Editorially, we repeatedly emphasize to our members the need to be constantly alert to the possibility of the existence of cancer in their patients regardless of age, and the necessity for the earliest possible diagnosis of malignancy. It is axiomatic that the earlier the diagnosis the more effective are our means of combating cancer with surgery, x-ray and radium. To this end, in 1952 a series of six articles was sponsored by our Committee on Research. These articles were solicited from leading cancer specialists and were designed to encourage the application of some of the latest methods for early cancer diagnosis in office practice.

At this junction I would like to note that so far I have been outlining solely the accomplishments of the American Medical Association in this professional educational field. By no means do I wish to imply that we are alone in carrying out this task. On the contrary, we are ably joined by the local and state medical societies which make significant contributions in this regard. The state and local medical societies in their publications and regular meetings include many discussions, articles, and papers on cancer. Each hospital's medical staff holds conferences and meetings on cancer and other medical problems.

Outside of our Association and affiliated groups, the American Cancer Society and its subsidiary state and local societies, as well as the National Cancer Institute, the Damon Runyan Foundation and special societies of both lay and professional people too numerous to mention join in this task.

The Association has been equally interested in the field of cancer research. For the past six years we have supported, with the cooperation of representatives of the drug industry, a far reaching survey of the effects of certain sex gland hormones and allied substances upon the course of various forms of cancer. We became interested in this program because it offered promise of a method of treatment, within the skill of most physicians, which would permit office or home care for the long-term cases of inoperable cancer of the breast, prostate gland and possibly other organs.

In 1946 when this program was inaugurated only a few breast cancer cases, treated with these endocrine substances, had been reported upon. It was imperative to learn as quickly as possible the efficacy of these agents, the best dosages and possible hazards in this therapy. It was obvious that no one physician or clinic could see enough cases in a relatively short period of time to accurately assess the problems outlined. It was equally obvious that if the benefits of this treatment were to devolve to patients suffering from cancer as quickly as possible, it was necessary to organize a cooperative study involving many clinics and investigators.

The Subcommittee on Steroids and Hormones of the Committee on Research undertook the organization and conduct of such a study. It is not my intention to comment on the mass of data which has been accumulated; however, certain pertinent facts concerning this study deserve mention. In all, 45 clinics and 65 investigators joined in the task. They deserve the majority of the credit for the results achieved. The pharmaceutical industry has also been extremely cooperative in supplying large quantities of expensive and, in some instances, rare substances for distribution through the Committee to investigators without charge. The American Medical Association bore all of the administrative costs plus the costs for biennial meetings including travel of all investigators.

This subcommittee was faced with problems of standardizing as far as possible the selection of proper patients for treatment in the various clinics. From their own experience, the members devised varying dosage schedules and designated the clinics which would use them. The investigators were furnished with standard forms so that their reports would be as uniform as possible. These reports were filed quarterly and the data was analyzed by the office staff of the Committee on Research in Chicago. Thus, in a relatively short time the medical profession was in possession of definite criteria for the selection of patients for this form of treatment plus definite dosage schedules which met the needs of the majority of their patients. In this way the dangers inherent in the therapy were also discovered in advance. This was accomplished by seven Committee publications in The Journal of the American Medical Association and approximately 100 individual publications.

It may be of interest to the Committee to know that over 2,000 inoperable breast cancer cases have been registered and treated. At the present moment an analysis of the total data accumulated is in progress with a view to the publication of the results as a series of monographs. Currently substances are being tested in the hope of finding more effective compounds with fewer side-effects. The studies themselves have been widened to include cancer of the female and male sex organs, the urinary bladder, the thyroid gland, and certain bone tumors. We should like to emphasize that each of our investigators is still a free agent. They are not bound rigidly to our organization. Each is free to conduct other research projects for other agencies even upon the forms of cancer in which we are primarily interested. All we ask of the collaborating investigators is that they report their results to our central office. These results are then disseminated among other investigators by means of bulletins and letters. Thus, it may be seen that the primary efforts of the American Medical Association as well as those of many other medical societies is towards the expeditious exchange of scientific and objective medical information.

The road to the solution of the cancer riddle is not an easy one since we know little about the actual cause or causes of this group of diseases. It is also unfortunate that all the problems in regard to cancer are not on the positive side, that is, imposed by the disease. There is instead a venal, negative side, with problems which are man made, created by those who seek commercial gains by foisting false hopes and cures on the cancer patient and his family. For over half a century the American Medical Association has shown bold leadership in opposing these forces. During this time we have maintained an agency for the collection and dissemination of information on nostrums and quackery. We feel this task to be a public duty in order to protect the laity and to furnish physicians with objective evidence as to the lack of value and the identity of the secret nostrums proposed as cures.

In this endeavor the Association, through its Bureau of Investigation, has cooperated closely with the various federal and state agencies charged with the enforcement of laws regulating the drug industry. We have also cooperated with the state agencies which have jurisdiction over the licensing of individuals who seek to follow either the practice of medicine or the other healing arts.

In turning the searchlight of truth upon these cancer quacks we have frequently become the defendant in a court of law. Thus, the Association has been obliged to spend large sums of money in the defense of such legal actions. It is significant, however, to note that although we have been sued for more than 40 million dollars over the years, we have been obliged to pay but one judgment and that, in the nominal sum of one penny.

This is a constant battle in which we have chosen to remain in the forefront. Even now several nostrums are being promoted to the public either on representation that cures are obtainable or that the proponents are experimenting clinically with something new and valuable in the management of cancer patients, particularly those beyond the conventional methods of treatment used by medicine.

In our efforts to educate and expose, we have been joined by the American Cancer Society, the National Cancer Institute, the Damon Runyan Foundation and the Food and Drug Administration in sponsoring the National Research Council's Committee on Cancer Diagnosis and Therapy. Inasmuch as the work of this Committee will be described in detail by other witnesses, suffice it to say that it gives the nation a sound method of evaluating proposed cancer cures and diagnostic aids. It is the intention of our Association to encourage and further every honest attempt to increase our knowledge about cancer, to continue our earnest efforts in the quick dissemination of such knowledge to our physician members and to foster the type of cooperative research program previously outlined.

This concludes my formal statement. I want to thank the Committee for allowing our Association an opportunity to testify on this most important subject. I shall be happy to answer to the best of my ability any questions which members of the Committee may have.

NEW A. M. A. PUBLICATIONS

A revised catalog of medical and health films is now available. The Committee on Medical Motion Pictures has also published an index of all motion picture reviews published in THE JOURNAL from September, 1946, to December, 1952. Both booklets are available on request from the Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10, Ill.

An attractive new pamphlet entitled "It's Your AMA" describes the many services that the American Medical Association performs for its members, for medical societies, and for the public. The brief illustrated pamphlet will be mailed to all A. M. A. members after Oct. 15 and in the future will be supplied to each new Association member. The pamphlet contains, for example, information on A. M. A. activities in the field of medical education, medical economics, evaluation of foods, drugs, cosmetics, and medical devices, legislation, health education, and postgraduate education. How the A. M. A. helps state and county medical societies by providing films, exhibits, recordings, and pamphlets, and information on any subject in the medical realm is described. Also stressed is the role of each individual physician in the work of the Association, pointing up the need for an active, informed membership, financial support, and loyalty.

JOINT MEETING ON RURAL HEALTH

Cooperation at the grass roots level between agricultural, medical, civic, and lay groups is necessary in order to obtain a still better understanding of rural health problems and to help solve them. This conclusion was reached during a recent joint meeting of the Advisory Committee, made up of members of various farm and agricultural organizations, and the Council on Rural Health. The chairman of the Council, Dr. F. S. Crockett, Lafayette, Ind., told the group: "The volume of rural health work in the country that has been done cannot be measured. We do not know the exact contributions that our Council has made, but we all feel that we have been traveling in the right direction. There have been phases that we have not emphasized sufficiently, but we have agreed that in the future each organization and this group collectively can do more in this activity to meet the needs of farm people. The major portion of our job is educational. It will require time and patience on the part of all groups involved. It only can be accomplished by cooperation at all levels, especially at the grass roots level."

The need for more physician participation at state and county levels was emphasized at the meeting. It was suggested that lay members talk with physicians to help interest them and that members of the Council devise ways and means through state and county medical societies of interesting physicians serving persons in rural areas. The importance of selecting members for the state and county rural health committees who have an understanding of and an interest in rural health was accentuated.

The advisory committee felt that national conferences have been most helpful in obtaining a further understanding of rural health needs but that there still is a problem of getting information to persons in rural areas. Advisory members were charged with the responsibility of making contacts within their associations to provide for closer cooperation between their groups and the members of the Council on Rural Health. It was suggested that county medical societies invite lay groups to meet with them in an effort to provide a better understanding of rural health problems.

The value of rural newspapers and farm journals as channels through which health information can reach more persons was emphasized at the meeting. More direct attention by the American Medical Association to informative news releases in lay language and the possibility of the regular distribution to rural newspapers and farm journals of lay-language articles on rural health problems by physicians were discussed. It was agreed that there is a need for greater understanding and use of prepaid medical and hospital insurance by rural populations. Each organization needs to develop a program to inform its membership of the availability and provisions of prepaid insurance. Directors of agricultural extension services and leaders of farm organizations can best be informed of organized medicine's interest in rural health problems, it was brought out, through organized medicine's participation in the meetings of these groups and through periodic contacts with these organizations.

Those who participated in the meeting were in accord that there was still a great need of the principles of "counciling together," although formal organization of "Health Councils" should be a secondary thought. It was suggested that a few interested groups get together informally to discuss rural health problems and, as the discussion groups progressed, additional organizations should be invited to join.

The advisory members present at the meeting were Mrs. Charles W. Sewell, Otterbein, Ind., member-at-large; Mrs. Charles DeShazo, Paul's Cross Roads, Va., Associated Women of the American Farm Bureau Federation; Mrs. J. Laning Taylor, Washington, D. C., National Milk Producers Federation; Miss Gertrude Humphreys, Morgantown, W. Va., agricultural extension services; Mr. Paul C. Johnson, Chicago, *Prairie Farmer* magazine; Mr. L. R. Neel, Nashville, Tenn., *Southern Agriculturist-Farm and Ranch* magazine; Mr. H. E. Slusher and Mr. Chester Starr, Jefferson City, Mo., Missouri Farm Bureau Federation; and Mr. Frank W. Peck, Chicago, the Farm Foundation.

THE OATH OF HIPPOCRATES

The Oath of Hippocrates is reproduced on this page in response to many requests.—Ed.

I swear by Apollo, the physician, and Aesculapius, and Health, and All-heal, and all the gods and goddesses, that, according to my ability and judgment, I will keep this oath and stipulation: to reckon him who taught me this art equally dear to me as my parents, to share my substance with him and relieve his necessities if required; to regard his offspring as on the same footing with my own brothers, and to teach them this art if they should wish to learn it, without fee or stipulation, and that by precept, lecture and every other mode of instruction, I will impart a knowledge of the art to my own sons and to those of my teachers, and to disciples bound by a stipulation and oath, according to the law of medicine, but to none others.

I will follow that method of treatment which, according to my ability and judgment, I consider for the benefit of my patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to anyone if asked, nor suggest any such counsel; furthermore, I will not give to a woman an instrument to produce abortion.

With purity and with holiness I will pass my life and practice my art. I will not cut a person who is suffering with a stone, but will leave this to be done by practitioners of this work. Into whatever houses I enter I will go into them for the benefit of the sick and will abstain from every voluntary art of mischief and corruption; and further from the seduction of females or males, bond or free.

Whatever, in connection with my professional practice, or not in connection with it, I may see or hear in the lives of men which ought not to be spoken abroad, I will not divulge, as reckoning that all such should be kept secret.

While I continue to keep this oath unviolated, may it be granted to me to enjoy life and the practice of the art, respected by all men at all times, but should I trespass and violate this oath, may the reverse be my lot.

ANNUAL CONFERENCE OF WOMAN'S AUXILIARY

The 10th annual conference of state presidents, presidents-elect, and national chairmen of the Woman's Auxiliary to the American Medical Association will be held at the Hotel LaSalle, Chicago, Nov. 18-20. The program comprises panel discussions on legislation, civil defense, organization, mental health, rural health, nurse recruitment, and the American Medical Education Foundation. The luncheon speakers will be Dr. Edward J. McCormick, President of the A. M. A., and Dr. Franklin D. Murphy, chancellor of the University of Kansas. The Friday program will be given at the A. M. A. headquarters, where several educational films will be presented. A tour of the headquarters building will follow luncheon there. Wednesday evening there will be a dutch treat dinner at the Edgewater Beach Hotel on the north side of the city.

DR. ELMER LEE HENDERSON

The following letter was recently received by Dr. Edward J. McCormick, President of the American Medical Association.

"The Board of Trustees, meeting at the 55th Annual Convention of the American Hospital Association in San Francisco, recognized the great loss to both the American Medical Association and the American Hospital Association in the death recently of that great leader in medical circles, Dr. Elmer Henderson.

"The Board of Trustees of the Association appreciated Dr. Henderson's efforts on behalf of hospitals. His passing is a great loss to all health agencies of this country."

appointed full time director of medical education by Beth-El Hospital, Brooklyn. Dr. Snapper came to Chicago about a year ago from New York, where he had served as clinical professor of medicine at Columbia University College of Physicians and Surgeons and as director of medical education at Mount Sinai Hospital.

Dr. Fulton to Deliver Ranson Lecture.—On Oct. 30, 4 p. m., Theta chapter of Phi Beta Pi, Northwestern University Medical School, will present the 24th annual Stephen Walter Ranson lectureship. Dr. John F. Fulton, Sterling Professor of the History of Medicine, Yale University School of Medicine, New Haven, Conn., will discuss "Contemporary Concepts of the Hypothalamus and Their Origin" at Thorne Hall, Superior St. and Lake Shore Dr. The lecture is open to physicians, students, and other interested persons.

KANSAS

Dr. William Menninger Honored.—The Alumni Association of Cornell University Medical College recently bestowed the award of distinction on Dr. William C. Menninger, Topeka, professor of psychiatry, University of Kansas School of Medicine, Kansas City, and general secretary, the Menninger Foundation, "in recognition of his notable achievements in the teaching and practice of psychiatry, whose life and work have brought honor and acclaim to his medical college." Dr. Menninger in World War II was director of the neuropsychiatry consultants' division, Surgeon General's Office. He received the Distinguished Service medal and Army Commendation ribbon, and is a Chevalier of the French Legion of Honor.

Course on Orthopedics and Physical Medicine.—Physical medicine in its practical application to orthopedic practice will be presented in the refresher course, "Orthopedics, Physical Medicine, and Rehabilitation," Oct. 26-28, at the University of Kansas Medical Center, Kansas City. The course is a part of the postgraduate medical study sponsored by the University of Kansas in cooperation with the Kansas Medical Society and the Kansas State Board of Health. Round-table discussions by guest instructors and the staff will be held at the close of each day's program: Monday, "Fractures"; Tuesday, "Amputation and Prostheses," "Backache"; and Wednesday, "Arthritis." Guest instructors include Drs. Alexander P. Aitken, Boston; James L. Beaver, Wichita; Walter P. Blount, Milwaukee; Miland E. Knapp, Minneapolis; Jesse T. Nicholson, Philadelphia; and William D. Paul, Iowa City.

LOUISIANA

University News.—At Tulane University of Louisiana School of Medicine, New Orleans, members of the freshman class recently presented a portrait of Harold Cummins, Ph.D., assistant dean and professor of anatomy, to the university. Members of the staff of the department of obstetrics and gynecology, both past and present, gave a portrait of their chief, Dr. Conrad G. Collins.——When the Nebraska State Medical Society held its "Tulane University Day," Dr. Isadore Dyer, professor of obstetrics, Tulane University of Louisiana School of Medicine, New Orleans, spoke on "Obstetric Aspects of Prematurity—Prevention and Management," Dr. Conrad G. Collins, professor of gynecology on "Ectopic Pregnancy," and Dr. H. Reichard Kahle, associate professor of surgery, on "Intussusception: Diagnostic and Therapeutic Considerations."

Personal.—Dr. Leon J. Menville, emeritus professor of radiology, Tulane University of Louisiana School of Medicine, New Orleans, was recently made an honorary member by the Radiological Society of North America. During the 38 years of its existence, the society has conferred this honor on only eight persons.——Dr. William A. Sodeman, professor of preventive tropical and semitropical diseases and hygiene, Tulane University of Louisiana School of Medicine, has been appointed chairman of the department of medicine at the University of Missouri School of Medicine, Columbia.——Dr. Harold J. Jacobs, formerly clinical instructor of internal medicine, Louisiana State University School of Medicine, New Orleans, has been appointed director of the cardiac and pulmonary laboratories and also director of medical education at De Paul Hospital, Norfolk, Va.

MAINE

Venereal Disease Clinics.—The state department of health and welfare, bureau of health, maintains facilities for the diagnosis and treatment of venereal diseases in the following locations: Augusta, Bangor, Bath, Belfast, Biddeford, Lewiston, Portland, Rockland, Rumford, Sanford, Waterville, Wilton, and Winthrop. Any physician wishing to refer an indigent person for diagnosis or treatment may obtain the name of the nearest clinic physician by contacting the department at the state house in Augusta. If no clinic facilities are available, physicians will be authorized to treat indigent patients in their offices. Authorization should be requested before treatment is started.

Clinical Session of State Association.—The fall clinical session of the Maine Medical Association will have its headquarters at Bangor House, 174 Main St., Oct. 25-26. Sunday, 6:30 p. m., Dr. Sara M. Jordan, chief of the gastroenterology section, Lahey Clinic, Boston, will address the dinner meeting for physicians and wives. Her subject will be "Digestion, Diet, and Doctors." The clinical program will be presented Monday at the Eastern Maine General Hospital, Bangor. Dr. Jordan will serve as guest moderator for the morning program, which includes orthopedic cases, gastric bleeding, intestinal polyps, regional ileitis, and fluid and electrolytes in surgery. Dr. Edward B. D. Neuhauser, roentgenologist, Infants' Hospital, Boston, will comment on the afternoon topics: selection of cases for cardiac surgery, infantile cortical hyperostosis, selected orthopedic cases from children and young adults, and mediastinal tumors. Dr. Neuhauser will discuss "Pediatric Roentgenology in General Practice" at the dinner Monday, 6:30 p. m.

MASSACHUSETTS

Personal.— The fourth annual Joseph L. Baer lecture, "Carcinoma in Situ of Cervix: Further Studies on Its Relationship to Cervical Carcinoma," was delivered before the Chicago Gynecological Society, Oct. 16, by Dr. Arthur T. Hertig, head of the department of pathology, Harvard Medical School, Boston.

New England Center Lectures.—The House Officers' Association, New England Center Hospital, is holding an evening lecture series. On Oct. 28, 7 p. m., Dr. Graham M. Bull, professor of medicine, Queen's University of Belfast, Belfast, North Ireland, will present "Postural Proteinuria" in the Stearns Auditorium, New England Center Hospital, Harrison Ave. and Bennet St., Boston. Discussors will be Drs. Alexander Leaf and Joseph M. Hayman Jr., Boston.

MICHIGAN

Beaumont Memorial.—The cornerstone for the Beaumont Memorial on the site in Mackinac Island where the Michigan State Medical Society is restoring the trading store of the American Fur Company, was laid on July 17 (see The Journal, May 3, 1952, p. 70; March 28, 1953, p. 117). Dr. Reader J. Hubbell, Kalamazoo, president, Michigan State Medical Society, the Hon. W. F. Doyle, Mackinac Island State Park Commission, and Dr. Otto O. Beck, Birmingham, chairman, Beaumont Memorial Fund, officiated at the cornerstone laying. Participating in the ceremony were Dr. William S. Jones, Menominee; Dr. Albert H. Miller, Gladstone; Dr. William Bromme, Detroit; Dr. Alfred H. Whittaker, Detroit; the Hon. G. Mennen Williams, governor of Michigan; the Hon. Leslie O'Brien, mayor of Mackinac Island; and the Rev. Thomas W. Murphy, Detroit. The ceremony commemorated the historical episode on June 19, 1822, when Dr. William Beaumont began the treatment of Alexis St. Martin for a gaping gunshot wound in the stomach and, through his observations on the gastric fistula became the first to study the process of digestion in life.

MEDICAL NEWS

CALIFORNIA

Symposium on Immunity.—Stanford University School of Medicine, San Francisco, will present a symposium on immunity and hypersensitivity, Oct. 30-31, under the sponsorship of the M and R Laboratories, Columbus, Ohio. There will be no registration fee. All meetings will be held in Lane Hall, 2398 Sacramento St., in the Medical School Building.

General Practitioners Meet in Coronado.—The California Academy of General Practice will hold its annual scientific assembly at the Hotel del Coronado in Coronado, Oct. 25-27. Among the out-of-state speakers are Dr. Louis A. Buie, Rochester, Minn., Dr. Raymond W. McNealy, Chicago, Dr. Frederic H. Bentley, former professor of surgery, University of Durham, England, and now lecturer in surgery, Sommer Memorial Trust, Portland, Ore., and Alfred C. Kinsey, Sc.D., Bloomington, Ind. The meeting is open to all members of the academy and to any nonmember physician on payment of a $5 registration fee. Information may be obtained from the California Academy of General Practice, Suite 900, 461 Market St., San Francisco 5.

Symposium on Heart Disease.—The San Francisco Heart Association will hold its annual symposium on heart disease at the St. Francis Hotel, San Francisco, Oct. 28-30. Dr. David A. Rytand, San Francisco, will moderate an electrocardiographic pathological conference Wednesday, 9-10:30 a. m. The Wednesday afternoon session will open with a panel discussion, "Therapy of Rheumatic Diseases," at which Dr. Lowell A. Rantz, San Francisco, will serve as moderator. It will close with a panel discussion, "Cardiac Involvement in Noncardiac Pediatric Conditions," moderated by Dr. Henry D. Brainerd, San Francisco. Dr. Alfred F. Goggio, Berkeley, will be moderator for the panel discussion, "Present Status of Modern Cardiac Surgery," Thursday morning, and Dr. Robert L. Smith Jr., San Francisco, for the panel discussion "Chronic Coronary Disease" Thursday, 3:45-5 p. m. "Cardiac Drugs" is the title of the panel discussion Friday, 11:15 a/m., for which Dr. Eliaser will serve as moderator. Friday afternoon will be devoted to a clinical session in the Nurses' Auditorium, Mount Zion Hospital, with Dr. Arthur L. Bloomfield presiding. Guest speakers and their first presentations include:

Robert H. Bayley, Oklahoma City, Possible Clinical Applications of Vectorcardiography.
Howard B. Sprague, Boston, Uses and Limitations of Ballistocardiography.
Ann G. Kuttner, New York (participant in panel on rheumatic diseases).
Howard B. Burchell, Rochester, Minn., New Techniques in Diagnosis of Congenital Heart Disease with Particular Regard to Dye Dilution Curves.
Herrman L. Blumgart, Boston, Pathology and Clinical Classification of Cardiac Pain.
Robert L. King, Seattle, Greetings from the President of the American Heart Association.
Eugene A. Stead Jr., Durham, N. C., Present Views in Circulatory Failure.

COLORADO

Dr. Joslin to Deliver Harvard Lecture.—The sixth annual Harvard lecture will be delivered by Dr. Elliott P. Joslin, Boston, in the Sabin Auditorium, University of Colorado Medical Center, Denver, Oct. 30, 5 p. m. His lecture, "Diabetes, Today and Tomorrow," is given under the auspices of the Rocky Mountain Harvard Medical Alumni Association.

Course on Fractures and Joint Injuries.—The orthopedic division, University of Colorado School of Medicine, Denver, will present this course Nov. 19-21, with Dr. Edwin F. Cave, associate professor of orthopedics, Harvard Medical School, Boston, as guest lecturer. The course is designed to present to general practitioners the most practical methods of treatment of fractures and dislocations and other traumatic conditions. Sessions will be held at Colorado General Hospital, Denver General Hospital, Fitzsimons Army Hospital, and Childrens Hospital, all in Denver. For information, apply to the Office of Graduate and Postgraduate Medical Education, University of Colorado School of Medicine, 4200 E. Ninth Ave., Denver 20.

DISTRICT OF COLUMBIA

Personal.—The Washington Heart Association has awarded its first clinical fellowship in cardiology to Dr. James J. Leonard.——The Ohio University Alumni Association has awarded a certificate of merit to Dr. James Alexander Lyon, Washington, D. C., "in recognition of distinguished attainments in the fields of internal medicine and cardiovascular diseases which reflect credit on his alma mater and are viewed with satisfaction by the Alumni Association."

University Receives Carrel Manuscript Collection.—The collection of manuscripts, comprising 60 cases of papers, amassed by the late Dr. Alexis Carrel has been donated to the Georgetown University Medical Center, Washington, D. C., by the surgeon's widow. Dr. Carrel, author of "Man, the Unknown," who collaborated with Charles A. Lindbergh on experiments in which tissues of a chicken heart were kept alive for several years in a mechanism constructed by the latter, was associated with the Rockefeller Institute for Medical Research from 1906 to 1939 and was member emeritus of the institute from 1939 until his death. Dr. Carrel was awarded the Nobel Prize in 1912 for his work in suturing blood vessels and the transplantation of organs.

ILLINOIS

Grants for Cerebral Palsy Research.—The United Cerebral Palsy Association has awarded three grants to the University of Illinois: (1) $19,313 for research in cerebral palsy with emphasis on disability evaluation and the application of physiological techniques for the facilitation of motor learning (under the direction of Dr. Frances A. Hellebrandt, department of physical medicine and rehabilitation); (2) $10,000 for investigation of the neuropharmacological aspects of cerebral palsy (conducted by Dr. Klaus R. Unna, department of pharmacology); and (3) $3,600 for a study of the treatment, designed to provide basic instruction in the clinical administration of cerebral palsy cases (under the direction of Beatrice D. Wade, O. T. R., department of occupational therapy).

Chicago

DeLee Lecture.—The Solomon Theron DeLee lecture, "Carbohydrates, Growth, and Pregnancy," will be given by Dr. Arthur St. George Huggett, professor of physiology, University of London, St. Mary's Hospital Medical School, at Chicago Lying-in Hospital, University of Chicago, 5841 Maryland Ave., Oct. 26, at 8:30 p. m.

Society News.—The Chicago Society of Industrial Medicine and Surgery will hold its fall scientific meeting at 8:30 p. m., Oct. 26, at the Palmer House (tel. RAndolph 6-7500). "The Emergency Care of Head Injuries" will be discussed by Dr. Harold C. Voris, clinical professor of surgery, neurosurgery division, Stritch School of Medicine of Loyola University. All persons of allied medical groups are cordially invited.

Dr. Snapper Returns to New York.—Dr. Isidore Snapper, director of medical education at Cook County Hospital and professor of medicine, Chicago Medical School, has been

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

appointed full time director of medical education by Beth-El Hospital, Brooklyn. Dr. Snapper came to Chicago about a year ago from New York, where he had served as clinical professor of medicine at Columbia University College of Physicians and Surgeons and as director of medical education at Mount Sinai Hospital.

Dr. Fulton to Deliver Ranson Lecture.—On Oct. 30, 4 p. m., Theta chapter of Phi Beta Pi, Northwestern University Medical School, will present the 24th annual Stephen Walter Ranson lectureship. Dr. John F. Fulton, Sterling Professor of the History of Medicine, Yale University School of Medicine, New Haven, Conn., will discuss "Contemporary Concepts of the Hypothalamus and Their Origin" at Thorne Hall, Superior St. and Lake Shore Dr. The lecture is open to physicians, students, and other interested persons.

KANSAS

Dr. William Menninger Honored.—The Alumni Association of Cornell University Medical College recently bestowed the award of distinction on Dr. William C. Menninger, Topeka, professor of psychiatry, University of Kansas School of Medicine, Kansas City, and general secretary, the Menninger Foundation, "in recognition of his notable achievements in the teaching and practice of psychiatry, whose life and work have brought honor and acclaim to his medical college." Dr. Menninger in World War II was director of the neuropsychiatry consultants' division, Surgeon General's Office. He received the Distinguished Service medal and Army Commendation ribbon, and is a Chevalier of the French Legion of Honor.

Course on Orthopedics and Physical Medicine.—Physical medicine in its practical application to orthopedic practice will be presented in the refresher course, "Orthopedics, Physical Medicine, and Rehabilitation," Oct. 26-28, at the University of Kansas Medical Center, Kansas City. The course is a part of the postgraduate medical study sponsored by the University of Kansas in cooperation with the Kansas Medical Society and the Kansas State Board of Health. Round-table discussions by guest instructors and the staff will be held at the close of each day's program: Monday, "Fractures"; Tuesday, "Amputation and Prostheses," "Backache"; and Wednesday, "Arthritis." Guest instructors include Drs. Alexander P. Aitken, Boston; James L. Beaver, Wichita; Walter P. Blount, Milwaukee; Miland E. Knapp, Minneapolis; Jesse T. Nicholson, Philadelphia; and William D. Paul, Iowa City.

LOUISIANA

University News.—At Tulane University of Louisiana School of Medicine, New Orleans, members of the freshman class recently presented a portrait of Harold Cummins, Ph.D., assistant dean and professor of anatomy, to the university. Members of the staff of the department of obstetrics and gynecology, both past and present, gave a portrait of their chief, Dr. Conrad G. Collins.——When the Nebraska State Medical Society held its "Tulane University Day," Dr. Isadore Dyer, professor of obstetrics, Tulane University of Louisiana School of Medicine, New Orleans, spoke on "Obstetric Aspects of Prematurity—Prevention and Management," Dr. Conrad G. Discussors will be Drs. Alexander Leaf and Joseph M. Hayman Jr., Boston.

MICHIGAN

Beaumont Memorial.—The cornerstone for the Beaumont Memorial on the site in Mackinac Island where the Michigan State Medical Society is restoring the trading store of the American Fur Company, was laid on July 17 (see THE JOURNAL, May 3, 1952, p. 70; March 28, 1953, p. 117). Dr. Reader J. Hubbell, Kalamazoo, president, Michigan State Medical Society, the Hon. W. F. Doyle, Mackinac Island State Park Commission, and Dr. Otto O. Beck, Birmingham, chairman, Beaumont Memorial Fund, officiated at the cornerstone laying. Participating in the ceremony were Dr. William S. Jones, Menominee; Dr. Albert H. Miller, Gladstone; Dr. William Bromme, Detroit; Dr. Alfred H. Whittaker, Detroit; the Hon. G. Mennen Williams, governor of Michigan; the Hon. Leslie O'Brien, mayor of Mackinac Island; and the Rev. Thomas W. Murphy, Detroit. The ceremony commemorated the historical episode on June 19, 1822, when Dr. William Beaumont began the treatment of Alexis St. Martin for a gaping gunshot wound in the stomach and, through his observations on the gastric fistula became the first to study the process of digestion in life.

MINNESOTA

Dr. Vadheim Appreciation Day.—Dr. Alfred L. Vadheim, Tyler, was honored by his community, which celebrated "Vadheim Appreciation Day" to mark the 43rd anniversary of his arrival in Tyler. Dr. Vadheim has served as mayor and as a member of the school board, has been active in Boy Scout work, and assisted in establishing the library. As Red Cross director for Lincoln County, he brought the county national honor in 1941 when it became the first in the world to become accredited for the control of tuberculosis.

Rigler Lecture.—The annual Leo G. Rigler lecture will be presented at the University of Minnesota, Minneapolis, Oct. 28, by Dr. Robert McWhirter, professor, department of radiotherapy, Royal Infirmary, Edinburgh. His subject will be "Simple Mastectomy and Postoperative Irradiation for Carcinoma of the Breast." Dr. McWhirter will also participate in the continuation course in radiation therapy which will be presented by the university, Oct. 26-31, under the direction of Dr. Leo G. Rigler and Karl W. Stenstrom, Ph.D.

MISSOURI

Society News.—The St. Louis Pediatric Society has elected Dr. Harry E. Wachter, president; Dr. Raymond J. LaDriere, vice-president; and Dr. Leo F. Gowen, secretary-treasurer. Meetings are held at Medart's Restaurant on the second Thursday of each month from October through May.——At the annual meeting of the St. Louis Ophthalmological Society, the following officers were elected: president, Dr. Harry D. Rosenbaum; vice-president, Dr. James H. Bryan; treasurer, Dr. Ruth S. Freedman; secretary, Dr. Anton J. Hummel; and member-at-large, Dr. Robert D. Mattis.

General Practitioners Meet in Jefferson City.—The Missouri Academy of General Practice will hold its annual scientific assembly at the Governor Hotel, Jefferson City, Oct. 28-29. At the Wednesday luncheon session, Dr. Ralph A. Kinsella, St. Louis, will present "Evaluation of Chest Pain." Other speakers on the Wednesday afternoon program include Drs. Henry R. McCarroll and Joseph C. Jaudon, St. Louis; Thomas E. McMillan, Kansas City; and Paul S. Williamson, Walsh, Colo. Dr. Roscoe L. Pullen, dean, University of Missouri School of Medicine, Columbia, will be guest speaker at the annual banquet Wednesday evening. Essayists on the Thursday program (Drs. Charles A. Brasher, Mount Vernon; Harry B. Stauffer, Jefferson City; Carl A. Moyer, St. Louis; William A. Sodeman, Columbia; and Paul S. Williamson, Walsh, Colo.) will also take part in a luncheon round-table discussion Thursday noon.

NEBRASKA

Dr. Kriz Presents Pool to Home Town.—Dr. Rudolph E. Kriz recently presented a $14,000 swimming pool to the city of Lynch whose citizens assisted in construction of the pool by furnishing labor and equipment for the excavating.

NEW HAMPSHIRE

Society News.—The New Hampshire Society of Anesthesiologists has elected the following officers for 1953: president, Dr. Frank G. Dudley, Littleton; vice-president, Dr. Angus M. Brooks, Concord; and secretary-treasurer, Dr. Agnes V. Bartlett, Springfield, Vt.

NEW JERSEY

Clinic for Amputee Children.—The Kessler Institute for Rehabilitation, Pleasant Valley Way, West Orange, will hold a free clinic for congenital amputee children and their parents Oct. 24.

Award to Dr. Orton.—The Academy of Medicine of Northern New Jersey presented its Edward J. Ill Award, to Dr. Henry B. Orton, professor of laryngeal surgery, New York Polyclinic Medical School and Hospital, New York. Dr. Orton is credited with having made important contributions in cancer of the larynx and, in his fight to prevent injuries to children from lye-containing household products, with having been instrumental in passage of a law by the state legislature of New Jersey, which requires that every product containing lye be marked poison.

Society News.—The New Jersey Allergy Society has elected the following officers for the coming year: president, Dr. Edward E. Seidmon, Plainfield; vice-president, Dr. William B. Nevius, East Orange; treasurer, Dr. Eugene J. Luippold, Boonton; and secretary, Dr. Frank Rosen, Newark.——At the annual meeting of the New Jersey Society of Clinical Pathologists, the following officers were elected for 1953-1954: president, Dr. Thomas K. Rathmell, Trenton; vice-president, Dr. George L. Erdman, Summit; and secretary-treasurer, Dr. Robert Brill, Passaic.——An award for "outstanding services to the society" was made to Elmer L. Shaffer, Ph.D., director of laboratories, New Jersey State Health Department. The program for the year includes tissue seminars, seminars in clinical pathology, and a special seminar in cooperation with the State Society of Medical Technologists.

NEW YORK

Hospital News.—The Mount Sinai Hospital, New York, announces that the weekly clinical pathological conferences by Dr. Paul Klemperer and Dr. Alexander B. Gutman and staff will be resumed Oct. 28, 3:30 p. m., and that weekly medical grand rounds by Dr. Gutman and staff will be resumed Oct. 30, 3 p. m., in the Blumenthal Auditorium of the Mount Sinai Hospital (entrance on Fifth Ave. at 99th St. through the hospital gardens).

Cardiac Teaching Day.—A postgraduate teaching day on heart disease for physicians and medical students will be held Oct. 29 at the Rochester Academy of Medicine, 1441 East Ave. At 2 p. m. Dr. Richard H. Lyons, Syracuse, will discuss "Treatment of Intractable Cardiac Failure," and at 3 p. m. Dr. Paul M. Zoll, Boston, will present "Recent Advances in Knowledge of Coronary Circulation." There will be a clinical pathological conference at 4 p. m.

Lecture on Chronic Arthritis.—At a meeting of the combined staffs of Binghamton City Hospital, Oct. 26, 8 p. m., at the hospital, Dr. Russell L. Cecil, professor of clinical medicine, Cornell University Medical College, New York, will discuss "The Treatment of Chronic Arthritis." This program of postgraduate instruction is arranged by the state council committee on public health and education, Medical Society of the State of New York, in cooperation with the New York State Department of Health.

Meeting of General Practitioners.—The annual scientific session of the New York State Academy of General Practice will convene at the Hotel Statler, New York City, Oct. 26-28. Each day's program will terminate with a round-table discussion at 3:15 p. m. by the speakers of the day: Monday, pediatric problems: Dr. Philip M. Stimson, New York City (poliomyelitis); Dr. John R. Cobb, New York City (orthopedic problems); Dorothy W. Baruch, Ph.D., Beverly Hills, Calif. (juvenile delinquency); and Dr. Samuel Karelitz, New York City (contagious diseases). Tuesday, adult problems: Dr. Walter C. Alvarez, Chicago (our neurotic population); Dr. Philip Thorek, Chicago (acute surgical emergencies in adults); Dr. Harold A. Abramson, New York City (psychosomatic allergy); Dr. Louis M. Hellman, Brooklyn (gynecologic problems); and Alfred C. Kinsey, Sc.D., Bloomington, Ind. (sexual behavior in the adult). Wednesday, geriatric problems: Dr. Edward J. Stieglitz, Washington, D. C. (patients, 70 years and older); Dr. Howard A. Rusk, New York City (rehabilitation of the aged); Dr. Alvarez (geriatric neuroses); Dr. Nolan D. C. Lewis, New York City (geriatric psychosis); and Dr. Louis H. Bauer, Hempstead (socioeconomic problems of the aged). Dr. Rusk and staff will hold a clinic at the Rehabilitation Center, Thursday at 10 a. m.

New York City

Hospital News.—The division of neoplastic diseases, Montefiore Hospital for Chronic Diseases, is presenting a series of conferences at 3 p. m. on the first Friday of each month in the social hall. On Nov. 6 "Endocrine Approaches to the Cancer Problem" will be the topic of Dr. Roy Hertz, chief, research medicine branch, National Cancer Institute, Bethesda, Md.

Lecture on Oral Pathology.—Lester R. Cahn, D.D.S., associate professor, oral pathology, Columbia University School of Dental and Oral Surgery of the Faculty of Medicine, will give a lecture, "The Practical Application of Basic Pathology: Inflammation and Repair," at the conference of the New York Institute of Clinical Oral Pathology, 9 p. m., Oct. 26, at the New York Academy of Medicine, room 440.

Cofer Memorial Chapel.—The Leland Eggleston Cofer Memorial Chapel, adjacent to the main entrance lobby of the New York Hospital, was recently dedicated as a nondenominational chapel in memory of Dr. Leland Eggleston Cofer, who died in 1948 after a distinguished career in surgery and public health, including such posts as commissioner of health of the Hawaiian Islands and commissioner of the port of New York. Mr. Hamilton Hadley, vice-president of the Society of the New York Hospital, thanked Mrs. Cofer and an anonymous donor for their gifts, which "have given us what we have not had in all our 182 years of history . . . a chapel."

Personal.—Dr. James Marion Bryant, who is in charge of inpatient cardiology on the fourth medical division of New York City's Bellevue Hospital, under the direction of Dr. Charles F. Wilkinson Jr., professor of medicine for the Post-Graduate Medical School of New York University-Bellevue Medical Center, has been appointed assistant professor of medicine at the school.——The Department of Defense, Washington, D. C., recently awarded a certificate of appreciation to Dr. Julius Lempert, surgical director of the Lempert Institute of Otology, who for several years has voluntarily accepted in his graduate classes specialists in otolaryngology from the Armed Forces Medical Services.

Course on Surgery of the Hand.—The New York and Brooklyn Regional Committee on Trauma of the American College of Surgeons announces a course on surgery of the hand, Dec. 11-12, 9 a. m. to 5 p. m. The course will be given at the Lenox Hill Hospital Einhorn Auditorium, 76th St. and Lexington Ave., by Drs. Joseph H. Boyes, Los Angeles; John H. Couch, Toronto, Canada; Michael L. Mason, Chicago; and J. William Littler, Robert H. Kennedy, Harrison L. McLaughlin, Ernest W. Lampe, and Thomas W. Stevenson Jr., all of New York. Advance registration is necessary. Communicate with Dr. Frederick M. Smith, Secretary, 180 Fort Washington Ave., New York 32.

NORTH CAROLINA

Lectures on Obstetrics.—A series of lectures on obstetrics has been arranged as part of a postgraduate medical course at Morganton, sponsored by the University of North Carolina School of Medicine, Chapel Hill, and the extension division, with the cooperation of a committee of physicians from Burke and adjoining counties. On Oct. 28 Dr. Edward A. Schumann, Philadelphia, will present "Toxemias of Pregnancy" at 4 p. m. and will discuss "Problems of Fetal and Neonatal Mortality" at 7:30 p. m.

NORTH DAKOTA

Meeting on Public Health.—The North Dakota Public Health Association will have its annual meeting at the Ray Hotel in Dickinson, Oct. 26-27. Featured speakers will include the Hon. C. Norman Brunsdale, governor of North Dakota; Dr. Charles F. Blankenship, regional medical director, U. S. Public Health Service, Kansas City, Mo.; and Dr. Russell O. Saxvik, state health officer, state department of health, Bismarck.

OHIO

Society News.—The sixth councilor district, Ohio State Medical Association, will hold its annual postgraduate day Oct. 28 at the St. Francis Hotel, Canton. Panel discussion topics include (1) "Infectious Diseases of the Pancreas and Chronic Relapsing Pancreatitis" and (2) "Chronic Ulcerative Colitis and Regional Enteritis." Among the panel members will be Drs. Robert M. Zollinger, Ohio State University College of Medicine, Columbus, moderator; Sara M. Jordan and Kenneth W. Warren, Lahey Clinic, Boston; Philip F. Partington, Western Reserve University School of Medicine, Cleveland; Everett N. Collins, and J. Beach Hazard, Cleveland Clinic. Papers will be presented by Drs. Jordan, Hazard, Partington, and Dr. Warren. Dr. Richard H. Overholt, Tufts College Medical School, Boston, will speak during the evening program on the subject, "The Fourth Dimension in Thoracic Surgery." Reservations may be made through Mr. E. M. Sprunger, executive secretary, Stark County Medical Society, 400 Fourth St., N. W., Canton 2.

OKLAHOMA

Meeting of Anesthesiologists.—Dr. Douglas W. Eastwood, St. Louis, will be guest speaker at the annual fall meeting of the Oklahoma Society of Anesthesiologists, Oct. 25, at the Oklahoma Club in Oklahoma City.

PENNSYLVANIA

Society News.—The Heart Association of Southeastern Pennsylvania is holding classes in dietary instruction for cardiovascular patients from the Philadelphia area in the Sheppard building of Woman's Hospital, Parrish and Preston Sts., on the first Tuesday of each month from 7 to 8 p. m. Any patient, private or clinic, whose physician believes he would benefit by professional guidance in following a reducing, salt free, or other type of special diet, is eligible to attend these classes. This free service is provided by the division of adult cardiovascular diseases of the Department of Health of the Commonwealth of Pennsylvania. Appointments may be made by contacting the Heart Association of Southeastern Pennsylvania, 1505 Walnut St., telephone LO 4-1185.

Philadelphia

Society News.—The annual meeting of the Philadelphia Allergy Society will be held Oct. 28 at the College of Physicians. Dr. Oscar Swineford Jr., Charlottesville, Va., will speak on "Background Observations on the Bacterial Allergy Problem." In a panel discussion, which will follow, Dr. Swineford will talk on "Asthma," Dr. Harry P. Schenck on "Allergic Rhinitis," and Joseph Smolens, B.S., on "Bacterial Antigens." Papers on allergy will be presented by Drs. David Myers and Alexander Sterling.

Pemberton Memorial Lecture.—The Philadelphia County Medical Society announces that the Ralph Pemberton Memorial lecture will be presented by Dr. Charles A. Ragan Jr., associate professor of medicine, Columbia University College of Physicians and Surgeons, New York, Oct. 29 at 9 p. m. His subject will be "The Pathologic Physiology of Bone and Joint Disease." The society will hold an afternoon program on therapy of the rheumatic diseases, beginning at 2 p. m. and terminating with a panel discussion at 4 p. m. Cocktails, 6:30 p. m., will precede a subscription dinner open to the medical profession.

SOUTH CAROLINA

Personal.—Dr. William S. Fewell has retired from general practice and will serve as full-time medical director of the Liberty Life Insurance Company, Greenville, S. C.

Society News.—At a recent meeting of the South Carolina Society of Anesthesiologists the following officers were elected: president, Dr. John M. Brown, Charleston; vice-president, Dr. Richard Wayburn, Columbia; and secretary-treasurer, Dr. George L. Timmons, Hartsville.

TEXAS

Hospital News.—The University of Texas Medical Branch in Galveston announces that completion of the new John Sealy Hospital building and of the Henry and Rosa Ziegler Memorial Hospital for diseases of the chest will increase the bed capacity of the medical branch hospitals from 700 to 1500. Opportunities are being offered for intern training in hospital administration under the direction of Mr. Edgar N. Cappleman, C.P.A., recently appointed acting administrator of the University of Texas Medical Branch Hospitals in Galveston.

VERMONT

Research Grants.—The National Institute of Health has awarded research grants totaling $46,920 to the following members of the faculty of the University of Vermont College of Medicine, Burlington: Dr. Eugene Lepeschkin, associate professor of experimental medicine, $15,380; Dr. Ethan A. Sims, assistant professor of medicine and biochemistry, and Dr. Kermit E. Krantz, assistant professor of obstetrics and gynecology, $12,181 for a study of renal function in pregnant women; Dr. Oscar S. Peterson, associate professor of radiology, $14,931 (continuing grant) for the development of rotational x-ray therapy, and Arnold H. Schein, Ph.D., associate professor of biochemistry, $4,428 for study of a chemical problem under the title "Purification of the Purine Oxidizing Enzymes, Xanthine Oxidase, Uricase, and Guanase."

Symposium on Cardiovascular Diseases.—At the annual meeting of the Vermont Heart Association, Oct. 26-30, in the Fleming Museum, Burlington, a symposium on cardiovascular diseases will be held in cooperation with the Vermont Heart Commission and the University of Vermont College of Medicine, Burlington. Monday, 9:30 a. m., Dr. Louis A. Selverstone, Boston, will present "Symptoms and Signs of Cardiovascular Disease" and at 2 p. m. will speak on congestive cardiac failure. At 4 p. m. there will be a case presentation on congestive cardiac failure at Bishop DeGoesbriand Hospital. Tuesday, 9:30 a. m., Dr. James H. Currens, Boston, will talk on electrocardiograms, and at 2 p. m. Dr. Gordon S. Myers, Boston, will discuss "Diagnosis and Management of Cardiac Arrhythmias." Case presentations on arrhythmias will be made at the Mary Fletcher Hospital, Durfee Clinic, 4 p. m. Wednesday morning Dr. James A. Evans, Boston, will discuss the diagnosis and medical management of hypertension, and in the afternoon Dr. Edwin F. Lang, Boston, will speak on surgical management, selection, and operative procedures in hypertension. Case presentations in hypertension will be made at the Durfee Clinic at 4 p. m. Thursday morning will be devoted to a paper, entitled "Pitfalls in the Diagnosis and Treatment of Cardiac Emergencies," by Dr. Conger Williams, Boston, and Thursday afternoon to a panel discussion on problems of the cardiac, for which Dr. George A. Wolf Jr., Burlington, will serve as moderator. The annual meeting of the Vermont Heart Association will be held at 4 p. m. Discussion of coronary disease by Dr. E. Hugh Luckey, New York, 9:30 a. m. Friday, will be followed by case presentations on coronary disease. Friday afternoon "The Rheumatic Fever Program" will be presented by Drs. Robert J. McKay and Olive M. Davies, Burlington, and "The Cardiopulmonary Diagnostic Clinic" by Dr. Donald B. Miller, Burlington. Formal opening of the Cardiopulmonary Clinic and a tour of inspection are scheduled at the Mary Fletcher Hospital at 3 p. m.

WASHINGTON

Meeting of General Practitioners.—The Washington chapter of the American Academy of General Practice will hold its annual convention and scientific session in the Chinook Hotel in Yakima, Oct. 30-31. Among the speakers will be Dr. Raymond W. McNealy, Chicago; Dr. Peter H. Forsham, San Francisco; and Mac F. Cahal, executive secretary of the American Academy of General Practice, Kansas City, Mo.

Fifty Year Buttons.—During its annual convention in Seattle the Washington State Medical Association awarded gold lapel buttons in recognition of 50 years of medical practice to Drs. Richard W. Perry, Fordyce C. Gorham, Clyde A. Fitzgerald, Francis M. Carroll, Herbert H. Canfield, David H. Houston, John E. Godfrey, Frank T. Maxson, Walter J. Howells, Park Weed Willis Sr., Maimon Samuels, and Lilian C. Irwin, all of Seattle; Leon L. Goodnow and Oliver R. Austin, Aberdeen; Herbert L. Underwood, Vancouver; Joseph E. Midgett, Des Moines; John P. Schutt, Bremerton; Arthur B. Cook, Anacortes; William A. Mitchell, Colfax; Charles E. Conway, Cashmere; Clyde E. Gray, Tacoma; Orme R. Nevitt, Raymond; and Harry E. Rhodehamel, Spokane.

WISCONSIN

Personal.—The following new members of the Wisconsin State Board of Medical Examiners have been named by Gov. Walter J. Kohler: Drs. John A. Schindler, Monroe, and Millard Tufts, Milwaukee, to replace Drs. Anthony F. Rufflo, Kenosha, and Ernest W. Miller, Milwaukee, whose terms ended July 1; Drs. Jerry W. McRoberts, Sheboygan, Thomas W. Tormey Jr., Madison, and Clifford A. Olson, Baldwin, to replace Drs. John W. Smith, Milwaukee, and Henry H. Christofferson, Colby, who resigned their positions, and to fill the position left vacant in 1951 by the death of Dr. Charles A. Dawson, River Falls.

University News.—The following promotions are announced by the University of Wisconsin Medical School, Madison: Dr. Ann Bardeen from instructor to assistant professor of anesthesia; in the department of medicine, Drs. Edgar S. Gordon and Marc J. Musser from associate professor to professor; Dr. Thomas H. Lorenz from instructor to assistant professor; Dr. John LeRoy Sims from assistant professor to associate professor; and Dr. H. Kent Tenney from associate professor to clinical professor (pediatrics); in the department of surgery (ophthalmology), Dr. Peter A. Duehr from associate professor to clinical professor of ophthalmology; Drs. John V. Berger and Frederick J. Davis from instructor to assistant clinical professor of ophthalmology; and Dr. Eleanor Maxine Bennett from instructor to associate professor.

Cancer Teaching Clinics.—Cancer diagnostic teaching clinics will be held at the Lutheran Hospital, Eau Claire, Oct. 27; the Memorial Hospital, Wausau, Oct. 28; and St. Elizabeth's Hospital, Appleton, Oct. 29. The following program will be presented, 2-5:15 p. m.:

Uterine Cancer, Roy G. Holly, Minneapolis.
Lung Cancer, Hiram T. Langston, Chicago.
Cytologic Diagnosis of Cancer, Gordon Worley Jr., Madison.
Oral Cancer, Frank D. Bernard, Madison.

At 6:30 p. m. there will be a dinner meeting with dentists (Eau Claire, Hotel Eau Claire; Wausau, Wausau Club; and Appleton, The Elks Club). Dr. Frank D. Bernard will present "The Dentist and the Physician—A Team in the Diagnosis of Early Oral Malignancies." Through funds made available by the American Cancer Society, Wisconsin division, these clinics are open to members of the State Medical Society of Wisconsin and Wisconsin State Dental Society without charge. Reservations are necessary for the dinner ($3). Requests should be sent to Dr. Anthony R. Curreri, Chairman, Committee on Cancer, SMS, 704 E. Gorham St., Madison.

GENERAL

Society News.—The annual meeting of the **American Academy for Cerebral Palsy** will be held Oct. 30-31 at the Western Hills Hotel, Ft. Worth, Texas. The scientific sessions are open to members of the medical or allied professions.

Meeting on Clinical Research.—The Central Society for Clinical Research will meet at the Drake Hotel, Chicago, Oct. 30-31. Dr. George E. Burch Jr., New Orleans, will deliver the presidential address during the Friday morning session. Participants in the 35 presentations that have been scheduled will include 49 speakers by invitation.

Meeting of Medical Colleges.—The Association of American Medical Colleges will hold its annual meeting at the Claridge Hotel, Atlantic City, N. J., Oct. 26-28, under the presidency of Dr. Ward Darley, Denver. The chief findings and recommendations of the survey of premedical education will be presented Tuesday at 10 a. m. by Aura E. Severinghaus, Ph.D., Columbia University College of Physicians and Surgeons, New York, and the chief findings and recommendations of the survey of medical education, at 2 p. m. by Dr. John E. Deitrick, Jefferson Medical College, Philadelphia. At 9 p. m. there will be a film program, medical audio-visual institute.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics; the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

Southwestern Medical Association.—The annual meeting of the Southwestern Medical Association is scheduled to be held at the Pioneer Hotel, Tucson, Ariz., Oct. 29-31. Presentations by guest speakers include:

William P. Thompson, Los Angeles, (1) Selection of Patients for Mitral Commissurotomy. (2) Prevention of Coronary Thrombosis. (3) Management of Congestive Heart Failure.
Donovan C. Browne, New Orleans, (1) Controversial Problems in Management of Peptic Ulcer. (2) Postgastrectomy Dumping Syndrome. (3) Management of Chronic Ulcerative Colitis.
Henry K. Ransom, Ann Arbor, Mich., (1) Diverticulitis of the Colon. (2) Surgical Treatment of Duodenal Ulcer. (3) Diseases of the Breast.

Drs. Edmund B. Spaeth, Philadelphia, Merl J. Carson, Los Angeles, and Marion B. Sulzberger, New York, will also participate in the program (subjects to be announced).

Meeting on Mental Health.—The National Association for Mental Health will hold its annual meeting at the Hotel Carter, Cleveland, Oct. 31 to Nov. 2. The theme of the conference, "Mental Health—Everybody's Business," will be introduced with presentation of "Everyone Has a Stake in Community Mental Health," by Dr. George S. Stevenson, national and international consultant of the association, which will be followed by a panel discussion at 10 a. m. At 12:30 p. m. Dr. Erich Lindemann, Boston, will discuss "Preventive Psychiatry for the Total Community" at the keynote luncheon in the Rainbow Room. Workshops on activities of mental health associations will be conducted at 2:30 p. m. On Sunday, 2:30 p. m. in the grand ballroom there will be a panel discussion, "Toward Greater Citizen Participation." At 8 p. m. in the grand ballroom there will be an open discussion on education in mental health. This will include idea exchange of educational activities used by state and local mental health associations in informing the public about mental health. Monday, 9 a. m., in the grand ballroom, a program on progress in improved care of the mentally ill will be presented. At 10:30 a. m. Dr. Walter H. Baer, Peoria, Ill., will be discussion leader for workshops on activities of mental health associations related to psychiatric aids. Dr. Paul Lemkau, Baltimore, will preside at luncheon in the Petit Cafe 12:30 p. m., at which the speakers will be Dr. William Malamud, Boston, director, NAMH research in dementia praecox, and Mr. Raymond G. Fuller, New York, director, study of administration of state psychiatric services. At 2:30 p. m. in the grand ballroom, Luther Woodward, Ph.D., director, community services, New York State Mental Health Commission, will have as his topic, "Rehabilitation of the Mentally Ill."

Southern Medical Association.—The 47th annual meeting of this association will be held at the Municipal Auditorium, Atlanta, Oct. 26-29. The opening assembly will be a public session Monday, 10:30 a. m., at which Dr. Walter C. Jones, Miami, Fla., president, will deliver an address, "Forgive Us Our Debts." His presentation will be followed by a discussion, entitled "Federal Medicine, Its Impact on the Medical Care of the American People," by Dr. Walter B. Martin, Norfolk, Va., President-Elect of the American Medical Association. On Tuesday the Hon. James C. Davis, representing the Fifth Congressional District of Georgia, will address the section on general practice at a luncheon meeting in the Dinkler Plaza Hotel, Civic Room, at noon. His subject will be "Socialized Medicine and Free Enterprise." The section on medicine will have a panel discussion Tuesday on newer techniques and problems in medical diagnosis and Thursday on the use of newer therapeutic agents. A panel on amebiasis will be presented by the section on gastroenterology Tuesday afternoon, and Wednesday morning the Southern Electroencephalographic Society will have a panel discussion on technique, instrumentation, procedures and problems in clinical electroencephalography. "Anesthesia in Urology" is the topic for the panel discussion to be presented Wednesday, 9 a. m., by the section on anesthesiology. The section on allergy has planned a round-table discussion on pediatric atopic dermatitis (eczema) for Tuesday afternoon. Wednesday afternoon "Research in the Clinical Center of the National Institutes of Health, Public Health Service," will be explained by Dr. William H. Sebrell Jr., Bethesda, Md., who will illustrate his talk with lantern slides. *Motion pictures will be shown in the Municipal Auditorium*, Tuesday and Wednesday, 9 a. m. to *5:30 p. m. The association dinner and dance will be held at* the Atlanta Biltmore Hotel, Wednesday, 7 p. m.

CANADA

Lecture on Thyroid Disease.—The 16th annual Louis Gross Memorial lecture, under the auspices of the Montreal Clinical Society, will be delivered at the Jewish General Hospital, Montreal, Quebec, Oct. 29, 8:30 p. m. by Dr. Martin M. Hoffman, associate professor of medicine and psychiatry, McGill University Faculty of Medicine, Montreal. The subject will be "The Physiopathology of Thyroid Disease."

LATIN AMERICA

Venezuelan Health Director to WHO Staff.—Dr. Carlos Luis Gonzalez, director of public health of Venezuela, has been appointed chief of the division of public health, Pan American Sanitary Bureau, Regional Office of the World Health Organization in Washington, D. C. Dr. Gonzalez has represented his country at most of the World Health assemblies and the meetings of the Directing Council of the PASB, serving as council chairman at its sixth meeting last autumn in Havana, where he was also a delegate to the First Inter-American Congress on Public Health.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy for Cerebral Palsy, Western Hills Hotel, Fort Worth, Texas, Oct 30-31. Dr. Harry E. Barnett, 116 S. Michigan Blvd., Chicago 3, Secretary.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Obstetrics and Gynecology, Netherland Plaza Hotel, Cincinnati, Dec. 14-16. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago 3, Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Cancer Society, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., *Providence 6, R. I., Secretary.*

American College of Cardiology, Hotel Statler, Cleveland, Ohio, Nov. 6-7. Dr. Philip Reichert, 480 Park Ave., New York 22, Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Knickerbocker, Chicago, Nov. 1-2. Dr. O. J. Pollak, P. O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of American Medical Colleges, Hotel Claridge, Atlantic City, N. J., Oct. 26-28. Dr. Dean F. Smiley, 185 N. Wabash Ave., Chicago 1, Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., *Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute* of Pathology, Washington 25, D. C., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 11-12. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Association of State and Territorial Health Offcers, Washington Hotel, Washington, D. C., Nov. 4-7. Dr. John D. Porterfield, 306 Ohio Depts. Bldg., Columbus 15, Ohio, Secretary.

Central Association of Obstetricians and Gynecologists, The Shamrock, Houston, Texas, Nov. 5-7. Dr. Harold L. Gainey, Suite 602, 116 South Michigan Ave., Chicago 3, Secretary.

Conference of Public Health Veterinarians, Hotel New Yorker, New York, Nov. 9. Dr. James Lieberman, U. S. Public Health Service, *Washington 25, D. C., Secretary.*

Congress of Neurological Surgeons, Roosevelt Hotel, New Orleans, Nov. 12-14. Dr. B. W. Cannon, 1092 Madison Ave., Memphis, Tenn., Secretary.

Interstate Post Graduate Medical Association of North America, Palmer House, Chicago, Nov. 2-5. Dr. E. R. Schmidt, 1300 University Ave, Madison 5, Wisconsin, Secretary.

Inter-Society Cytology Council, Philadelphia, Nov. 19-20. Dr. Paul F. Fletcher, 634 North Grand Blvd., St. Louis 3, Secretary.

Midwestern Section of American Federation for Clinical Research, Congress Hotel, Chicago, Oct. 29. Dr. Robert J. Glaser, 600 S. Kingshighway Blvd., St. Louis 10, Secretary.

National Association for Mental Health, Hotel Carter, Cleveland, Oct. 31-Nov. 2. Dr. George S. Stevenson, 1790 Broadway, New York 19, Medical Director.

National Society for Crippled Children and Adults, Palmer House, Chicago, Nov 12-14. Mr. Lawrence J. Linck, 11 South LaSalle St., Chicago 3, Secretary.

National Society for the Prevention of Blindness, New York, Dec. 18. Dr. Franklin M. Foote, 1790 Broadway, New York 19, Executive Director.

New England Obstetrical and Gynecological Society, Hotel Somerset, Boston, Oct. 28. Dr. Carmi R. Alden, 270 Commonwealth Ave., Boston, Secretary.

North Pacific Surgical Association, Victoria, B. C., Nov. 20-21. Dr. John A. Duncan, 509 Olive Way, Seattle, Secretary.

Oklahoma City Clinical Society, Oklahoma City, *Oct. 26-29. Miss Alma* F. O'Donnell, 512 Medical Arts Bldg., Oklahoma City 2, Executive Secretary.

Omaha Mid-West Clinical Society, *Hotel Paxton*, Omaha, Oct. 26-30. Miss Irene Rau, 1031 Medical Arts Bldg., Omaha 2, Executive Secretary.

Pacific Northwest Society of Pathologists, Eugene, Oregon, Nov. 6-7. Dr. John L. Whitaker, 315 South K St., Tacoma 3, Wash., Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 13-18. Dr. Donald S. Childs, 713 East Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Michigan, H. H. Rackham Auditorium, Ann Arbor, Dec. 5. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Governor.
- *Midwest—Ill., Ind., Iowa, Minn., Wis.—Hotel Schroeder, Milwaukee, Nov. 21. Dr Francis D. Murphy, 536 West Wisconsin Ave., Milwaukee 3, Chairman.*
- *New England—Conn., Maine, Mass., N. H., R. I., Vt.—Hartford,* Conn., Oct. 28. Dr. John C. Leonard, 80 Seymour St., Hartford 15, Conn., Chairman.
- *New Jersey, Trenton, Nov. 4. Dr. Edward C. Klein Jr., 73 Lincoln* Park, Newark 2, Governor.
- North Carolina, Chapel Hill, Dec. 3. Dr. Elbert L. Persons, Duke Hospital, Durham, Governor.

Regional Meetings, American Rheumatism Association:

- Ohio and Western Pennsylvania, Mayflower Hotel, Akron, Ohio, Nov. 11. Dr. Roger Q. Davis, 1405 Goodyear Blvd., Akron 5, Ohio, Chairman.

Southern Medical Association, Municipal Auditorium, Atlanta, Ga., Oct. 26-29. Mr. C. P. Loranz, 1020 Empire Bldg., Birmingham 3, Ala., Secretary.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 8-10. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Southwestern Medical Association, Pioneer Hotel, Tucson, Ariz., Oct. 29-31. Dr. C. C. Stapp, 800 Montana St., El Paso, Texas, Secretary.

Western Surgical Association, The Drake, Chicago, Dec. 3-5. Dr. Michael Mason, 154 East Erie St., Chicago 11, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. MacRae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Conference of International *Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954.* Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

Congress of International Anesthesia Research Society, Chateau Frontenac, Quebec, Canada, October 26-29. Dr. A. William Friend, 515 Nome Ave., Akron 20, Ohio, Chairman, Program Committee.

Congress of International Association for the Prevention of Blindness, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

Congress of *International Society* of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on *Thrombosis and Embolism, Basle, Switzerland*, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of Cardiology, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-15, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

International Congress of Clinical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A. Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, *Paris, Sept. 6-11, 1954.* Dr. Jean Bernard, 86 rue d'Assas, Paris 6^e, France, Secretary.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, *Belgrade, Yugoslavia, Secretary General.*

International Congress of Industrial Medicine, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

International Congress of Internal Medicine, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

World Federation of Occupational Therapists, Edinburgh, *Scotland*, August 17, 1954.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, July 16, 1954. Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.

American Board of Internal Medicine: *Oral.* Chicago, Nov. 30-Dec. 2. The closing date for acceptance of applications was April 1. *Written.* October 19. The closing date for acceptance of applications was May 1. Exec Sec.-Treas, Dr. William A. Werrell, 1 West Main St., Madison 3.

American Board of Neurological Surgery: *Oral.* New Haven, October. Final date for filing application was July 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, Kingshighway and Euclid Ave., St. Louis.

American Board of Neurology and Psychiatry: *Psychiatry and Neurology.* Dec. 14-15. Applications no longer being accepted. Chicago, April 29-30. Final date for filing application is Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Obstetrics and Gynecology: Written examination and review of case histories for all candidates will be held in various cities of the United States, Canada, and military centers outside the continental United States on Feb. 5. Case abstracts are to be sent by the candidate to the Secretary as soon as possible after receiving notification of eligibility to the Part I written examination. Application for *reexamination in Part II must be made prior to Feb. 1 of* any year. Sec., Dr. Robert L. Faulkner, *2105* Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Various Centers, January 25-26, 1954. Final date for filing applications was July 1. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 20-22. Final date for filing application was August 15. Final date for filing application for Part I is Nov. 30. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Pediatrics: *Oral.* Indianapolis, Dec. 4-6. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American *Board of Plastic Surgery: Entire Examination.* San Diego, Oct. 29-31. Final date for receipt of case reports was June 1. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Radiology: *Oral. Radiology, Roentgenology, Diagnostic Roentgenology and Therapeutic Radiology.* Chicago, Dec. 6-11. Final date for filing application was July 1. Sec., Dr. B. R. Kirklin, 102-*110 Second* Ave. *S.W.*, Rochester, Minn.

American Board of Surgery: *Part I.* Oct. 28, 1953. March 31, 1954 and Oct. 27, 1954. *Part II.* Chicago, Nov. 9-10; St. Louis, Dec. 14-15; Los Angeles, Jan. 11-12, 1954; Galveston, Jan. 15-16; Washington, Feb. 8-9; Cincinnati, March 8-9; New Orleans, April 12-13; Philadelphia, May 10-11; Boston, June 14-15. Sec., Dr. John B. Flick, 225 S. 15th St., *Philadelphia* 2.

DEATHS

Phaneuf, Louis Eusèbe ⊕ Boston; born in St. Hilaire, Quebec, Canada, Feb. 27, 1884; Tufts College Medical School, Boston, 1913; professor of gynecology at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology; chairman, Section on Obstetrics and Gynecology, American Medical Association, 1943-1944; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, of which he had been president, American Gynecological Society, New England Obstetrical and Gynecological Society, and the American Radium Society; fellow of the American College of Surgeons; corresponding member of the Société d'Obstétrique and de Gynécologie de Paris and honorary member of the Société Belge de Gynécologie et d'Obstétrique; surgeon-in-chief, gynecologic and obstetric department, Carney Hospital; surgeon-in-chief, department of gynecology, Boston Dispensary; consulting gynecologist, Beth Israel Hospital, Boston, Leonard Morse Hospital, Natick, Attleboro (Mass.) Hospital, Marlboro (Mass.) Hospital, and Henrietta D. Goodall Hospital in Sanford, Maine; consulting gynecologist and obstetrician, Fall River General and St. Anne's hospitals in Fall River, Mass.; consultant, Malden (Mass.) Hospital; in June, 1933, received the doctor of science degree from Tufts College; at the celebration of the centenary of l'Université Laval at Quebec City in 1952 he was granted the degree of doctor of medicine, honoris causa; died Sept. 20, aged 69, following partial gastrectomy for peptic ulcer.

Ferlaino, Frank R. ⊕ New York City; born Feb. 1, 1899; Johns Hopkins University School of Medicine, Baltimore, 1927; clinical instructor of public health, New York Medical College, Flower and Fifth Avenue Hospitals; specialist certified by the American Board of Internal Medicine; served during World War I; secretary of the council on postgraduate medical education, American College of Chest Physicians; district counselor for the Industrial Medical Association; member of the American Trudeau Society, American Public Health Association, and the American Heart Association; at one time chairman of the medical advisory board of the state athletic commission; member of the board of directors of the American Research and Education Foundation for Chest Disease; secretary and director of the Common Cold Foundation in Chicago; for many years medical director of the New York offices of General Motors; affiliated with Roosevelt Hospital; served as medical consultant to the Stony Wold Sanatorium in the Adirondacks, Lake Kushaqua, N. Y., and as associate medical director of Schenley Laboratories; associate editor of *Industrial Medicine and Surgery*; died in Long Island College Hospital Sept. 2, aged 54, of myocardial infarction.

Wilkinson, Robert Johnson ⊕ Huntington, W. Va.; born in Lynch Station, Va., in 1888; Medical College of Virginia, Richmond, 1912; member of the founders group of the American Board of Surgery; past president of the Southern Medical Association, of which he was vice-president, Southeastern Surgical Congress, the Association of Surgeons of the Chesapeake and Ohio Railway, Cabell County Medical Society, and the Alumni Association of the Medical College of Virginia; president of the West Virginia State Medical Association in 1943 and chairman of the state committee on medical education, the procurement and assignment committee, and the fact finding and legislative committee; fellow of the American College of Surgeons; at the time of his death, chairman of the committee arranging the program for the annual meeting of the International College of Surgeons at White Sulphur Springs in 1954; a director of the World Medical Association; served in the first volunteer medical corps, U. S. Army, during World War I; for many years physician in charge of the Chesapeake and Ohio Railway Employes Hospital; affiliated with St. Mary's Hospital; head of Wilkinson Surgical Clinic; died Sept. 14, aged 65, of coronary occlusion.

Liva, Arcangelo ⊕ Los Angeles; born in Italy in 1887; Eclectic Medical College of the City of New York, 1912; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; fellow of the International College of Surgeons and the American College of Surgeons; for 25 years a member, and formerly president of the state board of medical examiners; past president of the Bergen County Medical Society; affiliated with Hackensack (N. J.) Hospital; attending bronchoscopist, Newark Eye and Ear Infirmary in Newark, where he was affiliated with the Presbyterian Hospital; consultant in ophthalmology and otolaryngology, Bergen Pines, Bergen County Hospital in Ridgewood; in 1935 was awarded the honorary degree of doctor of medicine by the University of Rome; died Aug. 12, aged 66, of cerebral hemorrhage.

Barnes, Frank Haslehurst ⊕ Stamford, Conn.; born in Mohawk, N. Y., June 17, 1872; New York Homeopathic Medical College and Hospital, New York, 1896; past president of Fairfield County Medical Society and the Stamford Medical Society; member of the American Psychiatric Association; member of the medical advisory board in Stamford during World War I; specialist certified by the American Board of Psychiatry and Neurology; formerly on the faculty of the New York Post-Graduate Medical School; medical superintendent of Dr. Barnes' Sanitarium; consultant in psychiatry at St. Joseph Hospital and Greenwich (Conn.) Hospital; consulting neurologist at Stamford Hospital, where he died Sept. 14, aged 81, of hypertension, coronary occlusion, and carcinoma of the prostate.

Young, Richard Hart ⊕ Omaha; born in Columbus, Neb., Jan. 28, 1904; University of Nebraska College of Medicine, Omaha, 1930; professor of neurology and psychiatry at his alma mater; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association, American Psychopathological Association, and the Central Neuropsychiatric Association; affiliated with Methodist, Lutheran, Children's Memorial, Bishop Clarkson Memorial, and the University of Nebraska hospitals; died in University Hospital, Bellevue Medical Center, New York, Aug. 10, aged 49, of complications following surgery for Parkinsonism.

Blaisdell, Irl Hazard ⊕ Syracuse, N. Y.; born in Providence, R. I., March 10, 1911; Boston University School of Medicine, 1935; certified by the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; clinical associate professor of otolaryngology at the State University of New York College of Medicine at Syracuse; affiliated with City Hospital, Hospital of the Good Shepherd, and Syracuse Memorial Hospital; died near Watertown Aug. 1, aged 42, when his automobile was struck by a train.

Baker, Walter Eugene ⊕ Des Moines, Iowa; Drake University College of Medicine, Des Moines, 1907; affiliated with Iowa Methodist, Iowa Lutheran, and Mercy hospitals; died Aug. 29, aged 77, of lobar pneumonia and Parkinson's disease.

Bateman, Wilbert Charles, Zanesville, Ohio; Starling Medical College, Columbus, 1897; past president of the Muskingum County Academy of Medicine; for many years a member and for seven years president of the board of education of Zanesville; formerly city health officer; on the staff of the Bethesda Hospital and the Good Samaritan Hospital, where he died Aug. 29, aged 86, of arteriosclerosis.

Bernheim, Ruth Grace, Cincinnati; Laura Memorial Woman's Medical College, Cincinnati, 1902; for many years affiliated with the Jewish Hospital, where she died Sept. 11, aged 73, of carcinoma of the ovary with metastases.

⊕ Indicates Member of the American Medical Association.

Borgen, Alfred Edwin, St. Paul; University of Minnesota Medical School, Minneapolis, 1946; served during World War II; died near Duluth Aug. 8, aged 32, of accidental drowning.

Brainard, Benjamin F. ⊕ Martin City, Mo.; College of Physicians and Surgeons of Chicago, 1886; College of Physicians and Surgeons, medical department of the Kansas City University, Kansas City, Kan., 1904; an Associate Fellow of the American Medical Association; served on the staffs of Menorah and St. Vincent's hospitals in Kansas City; died Aug. 28, aged 89, of chronic myocarditis.

Brooks, Cadmus Marvin ⊕ Little Rock, Ark.; College of Physicians and Surgeons, Little Rock, 1910; clinical professor of anesthesia at the University of Arkansas School of Medicine; member of the American Society of Anesthesiologists; affiliated with the Arkansas Baptist State Hospital, where he died Sept. 2, aged 70, of carcinoma of the colon.

Carrico, Carl C. ⊕ Houston, Texas; Baylor University College of Medicine, Dallas, 1928; served during World War II; died in the Veterans Administration Hospital Sept. 7, aged 52, of encephalomalacia and thrombosis of multiple cerebral arteries.

Cook, Edgar Baldwin, Rochester, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1903; served during World War I; for many years associated with the Health Bureau as school physician and mental hygiene examiner; on the staff of the Genesee Hospital; died Aug. 20, aged 71, of arteriosclerosis.

Cowan, John Rice ⊕ Danville, Ky.; Harvard Medical School, Boston, 1894; fellow of the American College of Surgeons; affiliated with Ephraim McDowell Memorial Hospital; died Aug. 17, aged 81, of coronary occlusion.

Crowe, Robert Latta, Memphis, Tenn. (licensed in Tennessee in 1914); professor of pharmacology at University of Tennessee College of Medicine and in 1936 appointed dean of the school of pharmacy; died July 26, aged 65.

Cuneo, Peter Joseph ⊕ Bakersfield, Calif.; Cooper Medical College, San Francisco, 1911; for many years city health officer; died Sept. 1, aged 69, of cerebral hemorrhage.

Davis, Joseph Edward ⊕ Albion, Neb.; University Medical College of Kansas City, Mo., 1900; on the staff of the Boone County Community Hospital; died in Norfolk July 19, aged 79, of mesenteric thrombosis.

Deutsch, Isadore Herman ⊕ Oswego, Ill.; St. Louis University School of Medicine, 1925; affiliated with St. Charles Hospital, where he died Aug. 27, aged 56, of carcinoma of the lung.

Dyer, John H. ⊕ Warrenton, Mo.; Marion-Sims College of Medicine, St. Louis, 1892; for many years county coroner; died in St. John's Hospital, St. Louis, Sept. 5, aged 85, of arteriosclerotic heart disease and terminal pneumonia.

Eckhardt, Joseph Carl Augustus ⊕ Austin, Texas; University of Texas School of Medicine, Galveston, 1908; affiliated with Seton, Brackenridge, and Holy Cross hospitals; for many years physician for the Woman's Confederate Home; died Aug. 27, aged 70, of a heart attack.

Eyman, William George ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1903; fellow of the American College of Surgeons; on the staff of the South Side Hospital; died Aug. 30, aged 81.

Gano, Charles Harkness ⊕ Pittsburgh; College of Physicians and Surgeons, Baltimore, 1911; member of the Industrial Medical Association; died in the Presbyterian Hospital Aug. 13, aged 68, of cerebrovascular accident.

Gilbert, George Richardson, Omaha; Omaha Medical College, 1896; died Aug. 27, aged 79, of cerebral arteriosclerosis.

Giordano-Cortese, Modesto ⊕ San Francisco; Regia Universita di Napoli Facolta di Medicina e Chirurgia, Italy, 1916; served as an officer with the Italian Army during World War I; affiliated with Notre Dame Hospital and St. Mary's Hospital; died in Yountville, Calif., Aug. 18, aged 62, in an automobile accident.

James, Arthur Gregory Boswell ⊕ Bridgeport, Conn.; McGill University Faculty of Medicine, Montreal, Canada, 1927; on the staff of the Bridgeport Hospital; died Aug. 24, aged 57, of acute coronary thrombosis.

Klein, John ⊕ Chicago; Rush Medical College, Chicago, 1899; on the emeritus staff at St. Francis Hospital in Evanston, Ill., where he died Sept. 14, aged 83, of lymphosarcoma in the right axilla with metastases to the liver.

Lane, John David ⊕ Bennington, Vt.; Bennett Medical College, Chicago, 1909; an Associate Fellow of the American Medical Association; member of the New England Roentgen Ray Society; on the staff of the Putnam Memorial Hospital; died July 31, aged 73.

Lindsay, James Adams ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1909; chief of staff, St. John's Hospital; died Aug. 15, aged 69, of coronary occlusion.

Link, Joseph John ⊕ Mattoon, Ill.; Northwestern University Medical School, Chicago, 1920; fellow of the American College of Surgeons; served during World War I; for many years district surgeon for the Illinois Central and New York Central railroads; served as president of the staff at Memorial Methodist Hospital; a director of the Central National Bank; died in St. John's Hospital Aug. 29, aged 57, of hemachromatosis.

Mozley, Charles Almus, Albuquerque, N. M.; St. Louis College of Physicians and Surgeons, 1892; served as health officer of Sandoval County; died in Austin, Texas, Aug. 14, aged 81.

Norton, Alva C. ⊕ Rockwell City, Iowa; Rush Medical College, Chicago, 1895; died in Lutheran Hospital in Fort Dodge Aug. 18, aged 81, of carcinoma of the prostate.

Ragan, Romulus C. ⊕ Kansas City, Mo.; Medico-Chirurgical College of Kansas City, 1903; on the staff of the Trinity Lutheran Hospital; died in St. Luke's Hospital Sept. 8, aged 86, of acute cholangitis with hepatic abscesses.

Reinsberg, Karl ⊕ Mohawk, N. Y.; Philipps-Universität Medizinische Fakultät, Marburg, Prussia, Germany, 1923; president of staff of Ilion (N. Y.) Hospital; died July 30, aged 60, of coronary embolism.

Richardson, Anna Root Mann, Rochester, N. Y.; Boston University School of Medicine, 1901; for many years physician at Smith College in Northampton, Mass.; died in Rochester State Hospital Sept. 9, aged 75, of chronic myocarditis.

Schmidt, Florian Edward ⊕ Chicago; Northwestern University Medical School, Chicago, 1905; medical director of the Chicago Heart Association; formerly on the faculty of his alma mater; served on the professional staff of Lederle Laboratories, Inc., and later for nine years with Armour Laboratories; died Sept. 10, aged 69, of myocardial infarction and coronary sclerosis.

Scibetta, Samuel Louis ⊕ Erie, Pa.; University of Buffalo School of Medicine, 1917; fellow of the American College of Surgeons; at one time member of the school board; on the staff of Hamot Hospital and St. Vincent's Hospital, where he died Aug. 21, aged 60, of chronic leukemia.

Seyfried, Ernest A. N. ⊕ Nazareth, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1929; affiliated with St. Luke's Hospital in Bethlehem, Easton (Pa.) Hospital and Allentown (Pa.) Hospital; died Aug. 17, aged 49, of acute coronary occlusion.

DIED WHILE IN MILITARY SERVICE

Campbell, James McLain ⊕ Alexandria, La.; University of Tennessee College of Medicine, Memphis, 1933; for a short time with the Mississippi State Board of Health; served on the staff of the Veterans Administration Hospital; entered the U. S. Army Medical Service as a lieutenant colonel on July 1, 1953; died Aug. 5, aged 43, of coronary thrombosis while at home on a three day pass.

GOVERNMENT SERVICES

NAVY

Naval Hospital at Chelsea.—The Naval Hospital at Chelsea, Mass., where on Oct. 12-14 an important symposium for civilian physicians, as well as military medical officers, was held, was closely associated with early events in the history of our country. The hospital overlooks the Mystic River and historic Charlestown, Mass., and from this point women and children gathered to witness the battle of Bunker Hill in June, 1775. Many of the wounded in that battle were taken across the river, where beneath the trees that shaded what is now the hospital grounds the women dressed the wounds of the victorious Revolutionary soldiers. The area on which the city of Chelsea is built at that time was known as Winnisimmet. The first public ferry in the country was operated in 1631 between Winnisimmet, Charlestown, and Boston, the Winnisimmet landing being on the hospital grounds at the site of the present boat landing. It was not until 1823, however, that the commissioners of naval hospitals purchased 115 acres of land for $18,000 as the site of the proposed Chelsea Naval Hospital, and not until 1832 did Congress appropriate funds for the construction of this hospital. On Jan. 7, 1836, the Chelsea Naval Hospital was completed and placed in commission. The three-story hospital had a capacity of 100 beds. On the anniversary of the 118th year of service of this hospital last June, the historical account of the hospital noted that in 1896 a telephone was installed along with a steam disinfector and that a small room was fitted as a bacteriological, chemical, and microscopic laboratory. The laboratory was reported as "complete including microscope." The first major crisis to confront the hospital came with the pandemic of influenza during World War I when, with the rapid influx of patients, the number of beds was increased to 1,142. The Chelsea Hospital facilities were made available in 1920 to the Veterans Bureau, and in the decade that followed, Veterans Bureau admissions increased until they represented 75% of the total admissions. Again during World War II, the number of patients increased from around 279, before Pearl Harbor, to 2,700 patients, four years later. With minor changes in its routine it was adequate during the recent Korean fighting for all types of admissions from the battle front. The Chelsea Naval Hospital today stands on a windy hill some 112 feet above sea level where it maintains constant vigil over the health of men and women of the United States Navy.

Enlisted men's quarters. 8. Waves' quarters. 9. Officers' quarters. 10. Commanding officer's quarters. 11. Maintenance shops. 12. Storerooms.

Atomic Scientist Enters Army.—Dr. Maurice C. Fishler, head of the biological and medical sciences division of the U. S. Naval Radiological Defense Laboratory, San Francisco, has been ordered to military duty as a first lieutenant in the Medical Corps, U. S. Army. He reported for indoctrination at Brooks Army Hospital, Fort Sam Houston, Texas, the middle of October. Dr. Fishler joined the Navy laboratory in 1948 to organize the medical research program and has guided its activities ever since. For several years he has been a member of the Joint Panel on Medical Aspects of Atomic Warfare of the Research and Development Board.

PUBLIC HEALTH SERVICE

Dr. Daft Succeeds Dr. Wilder.—The appointment of Floyd S. Daft, Ph.D., as director of the National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, was announced October 12 by the Surgeon General. Dr. Daft, acting director of the institute since the resignation of Dr. Russell M. Wilder last June, has been assistant director and chief of laboratory research since 1951 and a member of the scientific staff of the National Institutes of Health since 1937. He has conducted nutrition studies, particularly on the B vitamins, and his investigations have contributed much to the understanding of dietary deficiencies causing anemia, cirrhosis of the liver, and other metabolic diseases. He was a pioneer in the study of an unidentified substance later shown to be folic acid. Before coming to the National Institutes of Health in 1937, Dr. Daft taught and engaged in research work at Harvard, Yale, the Carlsberg Laboratories, Copenhagen, Denmark, and the University of Rochester.

Personal.—Dr. Joseph O. Dean, formerly associate chief of the Bureau of State Services, Public Health Service, has been named assistant to the medical director of the Bureau of Indian Affairs, Department of Interior. Dr. Dean was appointed to the regular corps of the Public Health Service in 1929.

Regular Corps Examination for Medical Officers.—The Department of Health, Education, and Welfare, U. S. Public Health Service, announces that competitive examinations for the appointment of medical officers to the Regular Commissioned Corps of the service will be held in various cities throughout the country Feb. 2-4, 1954. The examination will include professional written tests, an oral interview, and a physical examination. Completed applications must be in the Washington office by Dec. 24. Appointments will be made in the grades of assistant and senior assistant, equivalent to navy ranks of lieutenant (j.g.) and lieutenant, respectively. Entrance pay is $5,686 for assistant surgeons with dependents, and $6,546 for senior assistant surgeons with dependents. This includes incentive pay, rental, and subsistence allowances. For application forms and additional information, write to: Department of Health, Education, and Welfare, Public Health Service, att.: Chief, Division of Commissioned Officers, Washington 25, D. C.

FOREIGN LETTERS

BRAZIL

Postoperative Jejunal Ulcer.—An etymological study on nomenclature of recurrent ulcers following gastric surgery was made by Dr. Eurico Branco Ribeiro, director of the Sanatorio São Lucas of São Paulo. The term "peptic ulcer," widely used by European authors, is strongly rejected because the ulcer is not caused by peptic digestion. The terms "marginal ulcer" and "anastomotic ulcer" are objected to because the ulcer is not located at the anastomotic ring but generally appears in the jejunum, near the new stoma. The better designation is "postoperative jejunal ulcer."

As a rule the ulcer is believed to be localized in the region most exposed to sudden attrition of the alimentary bolus. The nervous system is assumed to play a part in the pathogenesis, as changes in this system were seen to result in dysfunctions capable of contributing to the development of the ulcer. According to Dr. Ribeiro, in 22 years 28 operations were performed for postoperative jejunal ulcer in a total of 1,367 patients who had previously been treated surgically, i. e., 2.04%. This incidence can be reduced to 1.76% if two patients who both underwent three operations for recurrent ulcer are omitted from the series. Once the alimentary flow has been diverted, resection of the ulcer is not regarded as essential when the excision may impair the blood supply to the small intestine. When possible, however, resection is performed. In some patients vagotomy was done as a supplementary procedure. In one patient who was treated with vagotomy only, the pains recurred within eight months. There were four deaths.

Acute Obstruction in Megacolon.—Megacolon is common in central Brazil. Recently Dr. Oscar Barros Serra Doria pointed out the high incidence (28%) of acute obstruction in patients with megacolon. He believes that volvulus of the sigmoid is rarely the cause of the obstruction. Usually there is accentuated angulation at the rectosigmoid junction. He does not open the abdomen but treats these patients by means of a rectosigmoidoscope and a rectal tube.

Amebic Granuloma in the Large Intestine.—Seven cases of amebic granuloma of the large intestine have been reported by Dr. Haroldo Sodré and Dr. Júlio Croce. They found only nine similar cases in the Brazilian literature although intestinal amebiasis is very prevalent in this country. In the differential diagnosis they consider cancer, tuberculosis, mycosis, syphilis, schistosomiasis, regional enteritis, and paracolic inflammatory tumors. They always use emetine, and in some cases they use penicillin after a course of emetine treatment. This treatment has been very successful, as it cured all the patients in their series. They believe that surgical treatment has proved to be ineffective.

ISRAEL

Seventh International Congress of the History of Science.—The Seventh International Congress of the History of Science opened in Jerusalem on Aug. 4, 1953, and was attended by delegates from all over the world. Prof. F. S. Bodenheimer, of the Hebrew University, as Congress president welcomed the delegates from abroad. He stressed the importance of the study of the history of science for Israel and for the world, and called attention to some of the ancient and medieval scientific relics of the region.

Prof. Ben Zion Dinur, minister of education and culture, delivered the main address at the opening session on "The Value of the History of Science for Public Education." He dealt with the particular qualities of the history of science as a historical science and as an educational subject. "None compares to this science in its potential of education toward the unity of human society, mutual love and international harmony. The history of science includes the history of human thought, the methods of human observations, the ways of formulating conclusions. It is therefore incomparable as a means of developing in the younger generation the ability of independent thinking, of spiritual steadfastness, of constructive criticism, and of moral courage. For there is no courage as worthy of praise and honour as a man's courage to think independently and not in mere imitation of the teachings or traditions of others," he said. Professor Dinur felt convinced that "everything a man acquires from the history of science, in the process of the development and growth of man's spirit of seeking, will be multiplied a hundredfold in the spirit of divine wisdom in man, in the spirit of brotherly love, and of moral courage and civic strength."

Prof. G. Sarton, president of the International Academy of the History of Science, discussed "Science versus the Humanities; the History of Science." He said that the greatest problem of our age is "how to reconcile science with the humanities, how to bridge the growing abyss between well-meaning but ignorant idealists on the one hand, and uneducated technicians on the other." The solution, suggested more than a century ago and still valid, is in the study of the generalities of science and particularly the history of science. Scientific training is absolutely necessary, yet utterly insufficient. A man must be a scientist and a humanist at one and the same time. The New Humanism is an attack on nonhumanized scientists whose success would defeat civilization; and on Western scholars who deprecate Eastern efforts. He pointed out the suitability of Jerusalem as a good place to speak of this, for it is really at the very edge of the Arabic and Asiatic worlds.

The medical section was devoted entirely to Jewish or biblical topics. Dr. M. Sherman, president of the Israel Medical Association, discussed the history of medicine in Palestine in the 19th century. There was almost no medical care until 1838, when the European powers, to protect themselves, imposed on the Ottoman Empire a "Sanitary Administration" for purposes of establishing quarantine. The first hospital was founded in Jerusalem in 1843 by the London Society for the Promotion of Christianity among the Jews and the Rothschild Hospital, the first Jewish one, in 1854.

Dr. S. Muntner discussed the life and work of R. Shabbetai Donnolo (10th century), the first European medical writer in Hebrew. Dr. J. O. Leibowitz spoke on the life and work of R. Jacob Zahalon (17th century). Dr. S. H. Blondheim, of the Hadassah Hospital and Hebrew University Medical School, identified the epidemic among the Israelites at Beth Shemesh (I Samuel vi) as the first recorded epidemic of pneumonic plague. It is likely that this disease developed after the Israelites came into contact with the Philistines who suffered from the bubonic type of plague (Black Death) when the latter returned the captured Ark of the Covenant.

Physicians in Israel.—Israel had 3,717 physicians (including 710 women) and 903 dentists (including 359 women) at the end of 1952, the Central Bureau of Statistics and Economic Research revealed in a report based on a census of physicians and dentists. Germany heads the list of countries from which Israel has recruited its medical manpower, 992 physicians and 278 dentists having been trained in German universities and medical schools. More than a third of the physicians (1,278) are concentrated in Tel Aviv; Jerusalem is second in the number of physicians (603) and Haifa third (516). More than a third of the dentists (379) are also concentrated in Tel Aviv; Haifa is second in the number of dentists (127) and Jerusalem third (86). Less than half of the physicians (1,591) are general practitioners, and the remainder are specialists. Internal diseases and children's diseases head the list of the specialties.

The items in these letters are contributed by regular correspondents in the various foreign countries.

New Hadassah Departments in Plastic Surgery and Psychiatry.—The Hadassah Medical Organization will shortly establish departments in plastic surgery, neuropsychiatry, and rehabilitation, Dr. Kalman Mann, director of Hadassah Medical Organization, told the press recently. Prof. M. Rosenbaum of Cincinnatti University has arrived in Jerusalem to consolidate psychiatric work at present being carried out in the Hadassah University Medical School and to plan the new department, which is partially financed by the Schleider Fund, available in instalments of $15,000 annually.

Three physicians sent by Hadassah for training in plastic surgery, due to return soon from the United States, are to form the nucleus of a surgical team. They are Dr. Z. Rosen, specialist in nose and throat operations, Dr. J. Lewin-Epstein, specialist in jaw operations, and Dr. Z. Neumann, specialist in general operations.

The elements of the third new department, covering occupational therapy, physiotherapy, and general rehabilitation, are already in existence and have now been unified under the direction of Dr. E. Adler. Visualizing the hospital as a center of specialized therapy, Hadassah intends to provide daily health care through its local clinics, with the medical student learning from both central and peripheral institutions.

A building to house both a health clinic and cultural activities is to go up at the Beit Mazmil Community Health Center thanks to a donation of $100,000. This prototype health center, catering to 500 immigrant families in a Jerusalem suburb, benefits from the wider specialized care provided by the new hospital departments. Next year, medical students will begin to benefit from the community health center as a pilot plant for all-embracing family care. Instead of dealing with a few isolated cases, each student will be able to observe a number of family cases and thus relate medical problems to their environment. Dr. Mann said that after consulting with the Minister of Health, Mr. Y. Serlin, he had managed to coordinate the Hadassah teaching program with that of the government and other health agencies in Jerusalem.

ITALY

Convention of Rheumatology.—The seventh national convention of the Italian Society of Rheumatology was held in Florence last June under the chairmanship of Professor Villa. The first topic, prevention of rheumatic disease, was discussed by Professor Dogliotti, the director of the University of Turin Institute of Medical Pathology. Clinical observations and epidemiological studies of the last years have made clearer some aspects of the pathogenesis of rheumatic fever. The disease is preceded by respiratory infection due to some strains of hemolytic Streptococcus A in persons who are, in general, constitutionally predisposed to the disease and who live in an environment that favors its development. However, the pathogenetic mechanism that links the streptococcic infection to the complex tissue alterations characteristic of the rheumatic process (swelling and fibrinoid degeneration of the collagen, increased capillary permeability, and Aschoff's granuloma) and that are responsible in their evolution for the severe cardiac complications is not clear.

Although the Streptococcus infection recurs rather frequently in rheumatic patients, often producing clinical flare-ups of the disease, once the rheumatic process has begun it assumes a relatively autonomous course. This is continuous and progressive and is marked by flare-up periods that are improperly called relapses. These relapses are caused not only by the streptococcic infection but also often by other circumstances, such as physical overwork, changes of climate, diet intemperance, and emotional disturbances, that alter the reactive balance of the organism.

Long clinical experience has proved that sulfonamides and penicillin administered in repeated courses prevent the streptococcic infection and therefore the rheumatic disease. This type of prophylaxis can be applied to the many persons who are predisposed to the disease in particular circumstances only, as in epidemics of streptococcic infections. It is mainly indicated for prevention of the so-called relapses. When possible, penicillin should be preferred to the sulfonamides in that it is more active in causing the streptococci to disappear from the mucous membranes of the respiratory tracts without the development of penicillin-resistant strains of the bacteria. In addition, it is less likely to cause such dangerous toxic reactions as granulocytopenia.

Because of the current opinions about the pathogenesis of rheumatic disease, the use of tonsillectomy as a prophylactic measure is criticized. The intervention seems to be indicated only in the forms of chronic suppurative tonsillitis due to hemolytic Streptococcus in which penicillin does not provide a complete and definitive cure of the process. When the rheumatic disease is already in progress, tonsillectomy does not prevent its progress but only minimizes the probability of the so-called relapses.

Considering the great importance of the person's organic constitution for the development of the disease and the many etiological factors that may play a part in the relapses, anti-infectious prophylaxis is not sufficient. The patient's resistance may be increased by improving his diet and his environmental conditions. Besides this, the altered reactivity that is the basis for the pathogenesis of the disease may be corrected with the so-called antirheumatic therapy, namely, with salicylates, aminopyrine (Pyramidon), corticotropin, and cortisone. This therapy has an immediate beneficial effect on the acute manifestations, and, by preventing the exudative phase, it may limit the permanent secondary damages, especially those to the heart. Its preventive action has not been sufficiently proved, however, and studies are now in progress.

Organized and therefore better prophylaxis could be carried out by specialized centers that, in addition to establishing the best prophylactic method, should also be able to make a diagnosis in doubtful cases. A principal duty of the centers should be to spread information about the disease among physicians and the public. They should emphasize the diagnostic criteria and fundamental principles of therapy and prophylaxis, thus making known all the available means of prevention of severe damage to the heart. One of the main obstacles to the fight against rheumatic disease is the meager knowledge of the disease itself and the unsound conviction that it is impossible to prevent it or to influence its evolution and prognosis.

The second topic dealt with specific and nonspecific aspects of immunity in rheumatology. The immunologic study of acute and chronic rheumatic diseases is limited, mainly because of the lack of knowledge about the cause of the disease. Most research workers have admitted the existence of a varying reactivity that is almost unanimously identified as a state of sensitization; this concept, based on clinical data, has been supported despite the lack of exact etiological data.

A study was made to evaluate the conclusions reached in the clinical field and to establish the specific and nonspecific serum reactions of patients with rheumatic disease. Two criteria of research were followed: (1) determination of the specific factors (antigens and antibodies) and nonspecific factors (complement, conglutinin, and opsonin) of the known reactions of immunization, and (2) interpretation of the relation of the action of the antirheumatic drugs to immunization.

Considering the great importance of the nonspecific factors in the antigen-antibody reaction, the speaker studied the complex colloidal alterations of the plasma in rheumatic diseases in relation to the immunologic phenomena. The high antistreptococcic agglutinations that he observed in rheumatic disease was ascribed to an increase of the agglutinating factor of normal serum rather than to the existence of a corresponding antibody titer. The property that rheumatic serum has for nonspecific agglutination confirms the hypothesis that it is really a potentiation of the agglutinins that normally exist before the onset of the disease and not of recently formed immune antibodies.

Immunization reactions became negative following physical modifications of the serum that did not alter the true antibodies. The presence of protein C and similar substances that are not of an antibody nature confirmed the soundness of this concept, which finds the most typical paradigm in the Waaler-Rose reaction. All the tests that the speaker performed proved that the complement titer is increased during the active phase of rheumatic disease.

Considering the activity of antirheumatic drugs from the immunologic standpoint, these studies proved the inhibiting action of sodium salicylate and phenylbutazone (Butazolidin) on agglutination and hemolysis. Moreover, the doses of sodium salicylate that are used in therapy diminish the activity of the complement. Cortisone and corticotropin inhibit the specific and nonspecific factors of immunization. This activity follows a corresponding action on the synthesis of proteins.

The speaker examined also, with particular reference to the aspects of immunization, the favorable effects of jaundice and pregnancy on the rheumatic processes. As for jaundice, he cited the diminution of the complement activity as the expression of a deficiency in the synthesis of plasma proteins. Speaking of the good effects of pregnancy on the disease, he said that during pregnancy experimental anaphylactic shock does not appear, probably because of a decrease of the complement titer. Although it is certain that jaundice and pregnancy influence immunization by differing means, the relation of these processes to the pathogenesis of rheumatic diseases remains to be established.

LONDON

Nonresident Hospital Nurses.—The Standing Nursing Advisory Committee has responded to a request from the Minister of Health for advice and information on the question of whether there were any factors inherent in the work of a hospital nurse that made it necessary or desirable that she live in the hospital in which she worked or in nearby accommodation provided by the hospital authority. The committee considered that, subject to certain reservations in regard to particular grades, there were no factors inherent in a hospital nurse's work that made "living in" necessary. The most important reservations concerned the matron, the ward sister in charge of a ward for acute conditions, and the student nurse, especially in her first year of training. The committee also pointed out that the accommodation provided by a hospital authority for its resident nurses need not necessarily take the form of the traditional nurses' home; a useful alternative would be the acquisition of suitable large houses that could be rented to the nurses as single rooms or apartments.

"The King's Fund."—One of the most interesting, as well as one of the largest, medical charities is the King Edward's Hospital Fund for London, which was founded in 1897 by King Edward VII (then Prince of Wales) for the "support, benefit or extension of the hospitals of London." Its policy has always been to temper charity with caution, and it has never given grants to hospitals or associated institutions unless there was some guarantee that the money would be wisely spent. Such provisos, however, have never been of a negative or obstructive character, because the fund has always been willing to advise the hospital concerned on how to overcome the defects, whether administrative, accounting, nursing, or staff, and so be eligible for the grant that would be forthcoming when evidence was produced that the money would be wisely spent. This sage policy, originally initiated at the express wish of King Edward himself, has had two beneficial effects. One is that over the years the fund has accumulated a wealth of experience in hospital administration, hospital accounting, and nursing organization that has proved to be of value to the hospitals, not only in London but also throughout the country. The other is that the capital resources of the fund now amount to between 6 and 7 million pounds sterling. Expenditures during 1952 totalled £413,760. To outline all the activities of the fund would be impossible, and therefore only a few of its more important, or interesting, activities can be mentioned. These are of intrinsic interest, and in addition show the way in which the voluntary spirit is leavening the hard core of impersonal bureaucracy that now threatens to make the health services of the country very impersonal.

Hospital gardens are a new addition to the list of hospital activities subsidized by the fund, and during last year £3,000 was allotted to hospitals in the East End of London for this purpose. The initiative in this direction came from the hospitals themselves, and all that the fund has done has been to follow its traditional policy of encouraging and facilitating original and deserving ideas produced by hospitals. In order to ensure that the allotted sum is wisely spent, the fund has enlisted the help of both the Royal Horticultural Society and the curator of the Chelsea Physic Graden. An outstanding example of the initiative that the fund wished to encourage was the hospital in Shoreditch in the East End. This hospital has no grounds at all, but a yard has ingeniously been turned into a flower bed by raising a stone wall two feet high round the centre of the yard and filling the enclosed space with earth. Elsewhere in the hospital, flat roofs have been supplied with large boxes of earth. Thus, in the words of the fund's annual report, "though the hospital has no genuine soil, gardens have been provided for the patients, where they can sit and enjoy the sunshine."

Homes for the aged sick have been a special interest of the fund for several years. A sum of £350,000 has been set aside for the provision of 12 homes for the aged sick; these homes are to be under the wing of the hospital service of the National Health Service and are to be used for the accommodation of elderly patients until they become well enough to leave the care of the hospital service. The aim is to overcome the difficulty of so many hospital beds being occupied for long periods by elderly patients who are well enough to get up but not well enough to go home or to a residential home for old persons. Seven of the homes are now open, and all are successful. They are all attached to hospitals interested in old persons. This is considered essential: "The home must be linked with a hospital where the medical staff is actively interested in the care of the elderly. It is only in these hospitals that patients are found who need, as part of their treatment when they are on the road to recovery a stay in such a home." All of the homes are managed by voluntary organizations, mainly by the British Red Cross Society, while the local regional hospital board is responsible for maintenance costs. The medical care in the home is provided by the physician responsible for the elderly in the associated hospital.

Hospital accounting is a subject in which the fund has long and varied experience. It therefore accepted with alacrity an invitation from the Minister of Health to "carry out a complete unit costing of a small number of representative hospitals." This investigation has now been completed, and the principal recommendations are that (*a*) a departmental system of accounting be adopted, based on the units of organization of a hospital, e. g., departments, wards, and services; (*b*) budgets be prepared on the departmental system; and (*c*) all of the accounts be itemized in an income and expenditure account and a balance sheet prepared in accordance with recognized accounting principles. It is claimed that the adoption of this departmental system is the answer to the criticisms that, under the present system, it is not possible to ascertain the cost of maintaining any one of the numerous departments of a modern hospital and that the unit "cost per occupied bed" is futile for purposes of comparison between hospitals. "Under the departmental system a separate account is set up and maintained for each department. of the hospital organization and within each such account the expenditure is grouped under significant headings appropriate to the work of the department. Finally, the departmental expenditure is reduced to a cost per unit of service, such units being determined solely by the nature of the service rendered in each case. As, under the new system proposed, the budget is also departmentalized, the budgeted unit cost of each department becomes the 'yardstick' against which its actual cost will be measured." Hospital accounting, it is pointed out, is not mere bookkeeping; it is "an integral part of hospital administration. . . . It is the return obtained for expenditure and not the expenditure itself that is of vital importance, and the real problem of hospital finance, and its control, is to maintain productivity of expenditure at a maximum. A highly centralized rigid financial control of one side only of the equation—payments—is quite inadequate and inappropriate as, under it, success comes to be measured more by the degree to which expenditure is kept within the defined limits, than by the return obtained for the expenditure."

This section of the report concludes with some comments that are probably applicable elsewhere, as well as in the United Kingdom: "During the past half century hospitals have vied with one another in establishing new departments, in opening new clinics and in the over-elaboration of equipment, bringing about duplication and overlapping. In doing so, capital has often been wasted and maintenance costs have increased to unprecedented levels. Has not the time arrived for a backward swing of the pendulum; the time to resolve the balance of functions; the time for hospitals to ask not 'how much more can we get to spend' but 'how much can we reduce our demands?'"

Treatment of Poliomyelitis in Hospital.—A recent memorandum from the Ministry of Health makes recommendations for the arrangements to be made for the treatment of poliomyelitis in hospitals. Wherever practicable, poliomyelitis should be treated in hospital units with a highly trained and experienced team equipped to deal with the disease. Some concentration of cases in such units is essential, if the teams are to have sufficient work to give them the experience they require. The team should include a surgeon or physician competent to deal with respiratory complications and, most important, a senior resident of at least registrar grade, specially trained for this work, who would be available to be called in at a moment's notice to deal with the sudden changes that are a characteristic of the disease. Orthopedic advice should also be available at the unit, together with facilities for physiotherapy in paralytic cases. Nurses should have had training in the management of patients in artificial respirators as well as the commoner techniques. The concentration of cases in suitable units would, of course, be somewhat limited by the undesirability of long ambulance journeys during the acute phase of the disease. Facilities for isolation are more readily provided in hospitals for infectious diseases than in general hospitals, whereas the facilities for treatment are most readily available in general hospitals. Since hospitals for infectious diseases are usually included in groups with general hospitals and are now increasingly used in part as general hospitals, it should be practicable to provide the necessary treatment facilities in any large hospital for infectious diseases chosen to house a poliomyelitis unit. Failing this, a special unit might be provided in a general hospital, if adequate arrangements for isolation are practicable.

When a properly equipped and staffed special unit is not available within a reasonable distance, it may be necessary to arrange special separate isolation accommodation in other hospitals, e. g., general or orthopedic. The hospital selected should be within an hour's ambulance journey, preferably well within this limit.

Except in an emergency, acute cases of poliomyelitis should not be nursed in cubicles attached to children's wards, and all multiple bed isolation wards should have the customary 12 ft. (3.66 m.) between bed centers and a separate staff (if possible, living apart from the other nurses). Acute cases of poliomyelitis among the hospital staff should be segregated. No persons with confirmed cases of poliomyelitis should leave hospital within three weeks of admission. Poliomyelitis patients should not, however, be allowed to return to a susceptible community of children, such as a school, children's home, or day nursery, until six weeks after the onset of the disease.

PARIS

Congress of the International Association for Public Welfare.—The International Association for Public Welfare met on Sept. 21-26, 1953. The agenda included the following topics: recent developments in the field of public welfare, family allowances, evaluation of disablement, and relations between the institutions for public welfare and the medical profession. Permanent technical commissions met from Sept. 14 to Sept. 21. The medicosocial commission dealt with the following points: medical secrecy in public welfare legislation, and polypharmacy. The Commission for Mutual Insurance studied the possible means of contributing to the setting up of systems of social protection in backward countries by means of mutual insurance.

SPAIN

Antituberculous Crusade.—When the problem of tuberculosis in Spain is regarded from the economical and humanitarian points of view, it is evident that the losses the country suffers from this disease are enormous. While the monetary value of human lives cannot be determined, estimations can be made on the basis of the amount of money given to the family of those who are insured by the Compulsory Insurance for Travelers when the insured die in an accident. The amount given to the family for the death of an insured person, regardless of profession, sex and age, is 40,000 pesetas (11 pesetas equals about $1.00). On this basis the annual rate of 30,000 deaths from tuberculosis, represents a loss of 1,200 million pesetas. Adding to this amount the expenses during illness and the loss productive work, a figure of 1,500 millions of pesetas a year lost as a result of tuberculosis is reached. The budget of the National Antituberculous Department has constantly increased from 15 million in 1940 to almost 332 million in 1953.

The amount of money appropriated in the last year is fantastic. When the National Antituberculous Department was established in 1936, a bed in a sanatorium could be made available for 5,000 pesetas per bed and the daily expenses of hospitalization were 5 pesetas. At present, however, the approximate expenses for establishing a bed are 50,000 pesetas and the daily expenses of hospitalization are 28.56 pesetas. At present 280 more dispensaries are needed on the basis of one dispensary for every 100,000 persons. Administration of new antituberculous drugs has not reduced the number of sanatorium beds required. Patients receiving the new antituberculous drugs improve very much but they are not entirely cured and must remain in the sanatoriums.

It is difficult for certain groups and the heads of industrial centers to understand that the main purpose of the National Antituberculous Department is to organize as many sanatoriums and dispensaries as possible, to have in reserve the necessary technical personnel, and to administer the general educational crusade, all of which require the collaboration and economical resources of industrial corporations. For such collaboration and aid, these centers are given a certain number of beds in proportion to the aid they give. Efforts will be made to obtain close collaboration between administrators of health insurance and the National Antituberculous Department. While with the methods used at present these groups and the patients do not receive any actual benefit, they will do so as soon as the groups understand better the needs and privileges of each other.

Several sanatoriums are to be opened in the very near future in the following places: San Sebastian, Ferrol, Castellón de la Plana, El Escorial, Guadarrama, Bejar, and Linares. The sanatorium of Linares is for patients with silicosis. Sanatoriums are under construction in the following places: Logroño, Valladalid, Zaragoza, Burgos, Cadiz, Ciudad Real, Córdoba, Granada, Guadalajara, Huelva, León, Lugo, Alicante, Almería, Badajoz, Navacerrada, Madrid-Tablada, Soria, Teruel, Toledo, Las Palmas, and Tenerife. The efforts carried out in Spain in the antituberculous crusade are commendable. The cost of over 1,000 million pesetas has been provided during a time when the country was not very prosperous. The first and most enthusiastic crusader of this campaign is Dr. José A. Palanca, who is a professor of hygiene of the faculty of medicine of Madrid, the president of the National Antituberculous Department, head of public Health and chief of the Department of Sanitation of the Army, the Navy and the Air Force.

Medical Writing.—The Association of Spanish Physicians has organized a contest for writers and artists with the Premio Blanco award for this year. The award of 5,000 pesetas will be given to the author of the best work on art, history, or literature in relation to medicine. All physicians are invited to participate. Articles should be sent with duplicate typewritten copies, double spaced, before Jan. 1, 1954. They may be written in Spanish, Portuguese, French, Italian, English, German, or Latin. They should be sent with the name and address of the author in a sealed envelope to the Secretaria del Premio Blanco Soler, Fuencarral 113, Madrid, Spain.

CORRESPONDENCE

CHLOROPHYLL DERIVATIVES

To the Editor:—Since my original report on the use of specially prepared chlorophyll derivatives called "chlorophyllins" for the control of breath and body odors in 1950, much controversial literature has appeared. Your editorial is the first comment published by THE JOURNAL that has given my work any fair consideration. There are, however, several mistakes in this material that are the result of quoting persons whose information is outdated or who are misinformed.

According to Von Dobeneck, Willstatter called the mixture of saponification products of chlorophyll, which still contained complex magnesium, chlorophyllins before he identified the components. This term has since been discarded in favor of a more precise description of the saponification products. The removal of magnesium from "chlorophyllin" does not lead to pheophorbides but to chlorins, i. e., chlorin e_6 and rhodin g_7. Most commercial products contain copper complexes of chlorine. The manufacture of these commercial products is in the true sense a very complex procedure, and the analysis of the mixture of chlorins deriving from chlorophyll a and b has been an extremely difficult task, on which Von Dobeneck plans to report soon. P. Rothemund also states that only the magnesium salts of chlorophyll can be called chlorophyllins. I agree that one must insist on the use of correct nomenclature; however, I also believe that this can be accomplished only by discarding obsolete terms and using the universally accepted nomenclature of Hans Fischer. One of your correspondents recently put forth a blanket indictment on all deodorization tests but did not make a specific reference to any particular published test. He is apparently also unfamiliar with Harrisson's paper (read before the Society of Cosmetic Chemists, December, 1952, and published in the *Journal of Cosmetic Chemists,* March, 1953), which completely answers his criticism that professional odor experts cannot transfer their techniques to the examination of breath odors. Dr. Harrisson's paper outlines in detail the care taken to train testers to recognize certain concentrations of different odors on the "stinker" breath.

Brocklehurst in his experiments used preparations of unknown character, and unless he used materials and techniques that are accepted as standard in other papers he cannot be regarded as refuting anyone's work in this field. In in vitro tests there must be intimate contact between chlorophyllins and odors to be neutralized, not just their emanations, as in his bell experiments. Corwin himself is mistaken in his report, because in none of my papers have I tried to explain how chlorophyllins work, and I admit to not knowing. In vitro I know that chlorophyll has no oxygen liberating power and certainly none when ingested. Its systemic action cannot be laid to a bacteriostatic property, because not enough is ingested for this purpose.

F. HOWARD WESTCOTT, M.D.
130 E. 67th St., New York 21.

To the Editor:—We believe an editorial in THE JOURNAL, Aug. 29, entitled "Chlorophyll as a Deodorant" contained inaccuracies that should be corrected.

1. A source (K. V. Thimann: *personal communication*) was given to the effect that "commercial water-soluble chlorophyll preparations . . . are believed to be copper or nickel pheophytins. . . ." This is incorrect, since the water-soluble chlorophyll derivatives used in commercial preparations do not contain the pheophytin fraction.

2. Reference was made to a statement attributed to E. R. Weaver of the National Bureau of Standards to the effect "we have no reason whatever to believe that chlorophyll ever has anything to do with deodorization." This reference, taken out of context, failed to make clear that Weaver's statement applied only to chlorophyll-containing products used as air fresheners. The Bureau of Standards, March 27, 1953, authorized the following statement: "The statement 'we have no reason whatever to believe that chlorophyll has anything to do with deodorization,' appearing in circular 491 of the National Bureau of Standards was intended to relate only to the deodorization of air. The context of the statement clearly indicates the intended meaning. While it was known to the Bureau that chlorophyll and chlorophyll preparations have been applied directly to diseased and injured tissues, the Bureau has no data on such applications and did not intend to express or imply an opinion, either favorable or unfavorable, as to their merits."

3. References were made to a report by Brocklehurst in the *British Medical Journal* and to his conclusions on the deodorant properties of "chlorophyll." A review of the Brocklehurst paper shows that he did not characterize the material used in his work; therefore, since it cannot be duplicated, there is no basis on which to evaluate his findings. Also, either Brocklehurst's description of the odorous substance (methylmercaptan) is in error or he did not produce the material in the fashion he reported, because methylmercaptan is not produced from the starting material he used. If the odorous substance was not methylmercaptan, there is no assurance that the chemical indicator he used would have indicated a change in the odorous substance.

Finally, Brocklehurst employed primarily a nitrogen atmosphere for his experiments. There have been some deodorizing effects reported in the water-soluble chlorophyll derivatives in a nitrogen atmosphere, but these have not been of the same proportion as the effects reported in air. The use of a nitrogen atmosphere minimized the investigator's chances of recording a positive result under normal conditions. Also, in refutation of Brocklehurst's report there has been work done by various American investigators at the University of Alabama, Purdue University, and elsewhere that seem to have been more thoroughly done and whose findings were contrary to those of Brocklehurst.

Perhaps your original editorial was directed at the deodorant properties, as claimed, by various tablets, mouth washes, tooth pastes and similar "chlorophyll"-containing products. However, we believe it should not imply a question of the deodorizing and other properties, within the claims allowed by the Council on Pharmacy and Chemistry, of the ethically promoted Chloresium ointment and solution, which products carry the Council's Seal of Acceptance. These claims have been allowed and these products are accepted for advertising in THE JOURNAL.

O'NEILL RYAN JR.

7 N. MacQuesten Parkway
Mount Vernon, N. Y.

To the Editor:—In a letter "Chlorophyll as a Deodorant," published in your June 27 issue, Prof. K. V. Thimann comes to the conclusion that chlorophyll derivatives have no significant deodorant capacity. I have been working on this problem for more than a year. I presented a paper on the subject at the Federation Meetings in April in Chicago, and I think the data have been ignored by Professor Thimann.

We have investigated the deodorant capacity of well over 70 chlorophyll derivatives. In all instances we used an objective testing method. The procedure reported at the Federation of Societies for Experimental Biology, April, 1953, describes a recirculation system that proved suitable for large samples. Since that time, however, we have found it desirable to check chlorophyll derivative samples of approximately 30 mg. For this purpose we constructed a large water bath in which we could rotate 250 cc. glass tonometers at a constant temperature. In most of our work we used hydrogen sulfide as the odoriferous gas. The results so obtained were then checked in several instances using mercaptans with identical results.

The procedure is as follows. Thirty milligrams of the chlorophyll derivatives are dissolved in 1 cc. of distilled water. This solution is then drawn by vacuum into the clean dry tonometer. The tonometer is then evacuated to a standard pressure and attached to a bag containing approximately a 5% hydrogen sulfide mixture in air. The valve of the tonometer is opened, permitting a predetermined volume of the gas mixture to flow into the evacuated tonometer. The tonometer is then placed in the water bath at 34 C and slowly rotated for 30 minutes. At the end of that time the gas in the tonometer is pulled through an iodine solution and then back-titrated with thiosulfate. Since the concentration of hydrogen sulfide in the tube before contact with the chlorophyll derivative was known, it can be compared with the value obtained after contact. The difference between the two values, that is, the percentage reduction in hydrogen sulfide, is taken as a measure of deodorant capacity.

The procedure described above was designed to give approximately 50% reduction with a standard chlorophyll derivative because we wanted to test the effectiveness of different samples. Allow me to point out that the more potent derivatives give as much as a 70% reduction in the concentration of the hydrogen sulfide upon immediate contact with the chlorophyll solution. I think these experiments indicate conclusively that the chlorophyll derivatives are capable of deodorizing, since they effectively alter odoriferous gases such as hydrogen sulfide and the mercaptans.

We also carried out a few in vivo experiments in which we determined the concentration of scatol in the feces of dogs given chlorophyll derivatives orally. In every instance there was a significant decrease in scatol concentration, which supports the dramatic clinical findings in colostomy patients.

There is no question but that the subjective procedures that are in current use for evaluating deodorants leave much to be desired, and there is also no question but that chlorophyll products have been promoted in very dubious ways. However, when the chlorophyll derivatives are made available at the right place, in the right form, and in adequate concentration they do function, I believe, as extremely effective deodorants.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Foods and Drugs Differentiated By Intended Use.—The defendant was charged with a violation of the medical practice act in that she had administered drugs while holding a license to practice one of the limited branches of medicine. From a judgment of conviction, the defendant appealed to the Supreme Court of Ohio.

After examining and treating a patient by chiropractic methods, the defendant advised the patient about her diet and said that she should drink fennel and sage tea during the day, that she should drink only boiled water or Minnehaha Water, that certain vegetables were infested with spray poison, and that she should drink either raw milk or goat's milk. The defendant then gave the patient two little packets of pills, an order blank with a designation GE 8, and a list of vegetables that could be eaten without washing. The two packets of pills contained only lactose, or milk sugar, with a small amount of common salt, and the preparation GE 8, purchased by the patient from the Basic Endocrine Sales Company, contained "cholesterol, cerebrocides and lacithin, brain substance material along with some vegetable fiber."

The defendant contended, among other things, that the trial court erred in charging the jury that "fennel and sage are used in the United States Pharmacopoeia as drugs and, therefore, come within the definition of drugs," and that it would take judicial notice that fennel and sage were not foods. The defendant also claimed as error the action of the trial judge when he answered in the affirmative the jury's interrogatory as to whether fennel and sage used as tea are still considered drugs.

The Supreme Court pointed out that there was no evidence with reference to anything in either the official "United States Pharmacopoeia" or the official "National Formulary." Furthermore, it was admitted that the 1950 edition of the "United States Pharmacopoeia" failed to disclose the listing of fennel, although it was listed in the "National Formulary," and that sage was not listed in either the pharmacopoeia or the formulary. Nevertheless it was contended by the state that the judge could take judicial notice of the contents of these publications and that he could inform himself in any way that may seem best to him concerning subjects of which he may take such notice.

Assuming, said the Supreme Court, that the trial court may take judicial notice of what is listed in the pharmacopoeia and formulary, it is still not sufficient under the definition of "drug" contained in the General Code, that the article merely be recognized in the pharmacopoeia or formulary. To make such an article a "drug" it must, in addition, be intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or animals. To constitute any article a "drug" that is not so listed, it too must be intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or animals. Therefore, continued the Supreme Court, the charge that an article is a drug, simply because it is listed in the pharmacopoeia or formulary, without qualifying it by its intended use, is an incorrect statement under the law of Ohio, and the court committed prejudicial error in so charging. There is no question that certain articles may be either food or drugs, depending on their intended use.

The state contended that the defendant practiced medicine when she advised the patient to drink only boiled water or Minnehaha Water and alleged that distilled water is listed in the latest edition of the "United States Pharmacopoeia." Assuredly, said the court, boiled or spring water would not of itself be a drug under the statutory definition unless it was intended for the uses outlined in the statute.

The defendant insisted that all the advice and articles that she gave to the patient either concerned or were articles of food, and that there was no evidence to contradict this. In fact, the trial court indicated to the jury that peas, lima beans, corn, potatoes, carrots, raspberries, blueberries, bananas, rye bread, raw sugar, goat's milk, raw milk, and Minnehaha Water are foods, although fennel and sage are not. As we have said, concluded the Supreme Court, there is not a scintilla of evidence to dispute the statements of the defendant that all the articles with which the present case is concerned are foods, and there is not a scintilla of evidence that they were intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease.

In view of the fact that there was positive testimony that all articles given or recommended to the patient were foods, that they were not intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease, and that the articles in question can not be said to be food as a matter of law, the Supreme Court held that there was an entire lack of proof to sustain the verdict. Accordingly the judgment of conviction against the defendant was reversed. *State v. Winterich, 105 N. E. (2d) 857 (Ohio 1952).*

Hospitals in General: Injury to Patient Following Collapse of Adjustable Chair.—The plaintiff filed suit for personal injury suffered by her while a patient in the defendant hospital and alleged the injury was caused by the defendant's negligent failure to furnish a safe appliance and equipment for her use. From a judgment for the plaintiff, the defendant appealed to the supreme court, appellate division, that reversed the judgment. The plaintiff, therefore, appealed to the Court of Appeals of New York.

The plaintiff entered the defendant hospital as a patient after an accident in which she had suffered a fracture of the neck of the right femur where it enters laterally into the right hip socket of the pelvic bone. When surgery had accomplished the pinning of the fractured bone in apposition and in good alignment and a period of convalescence had passed, the plaintiff was permitted at times to sit in a wheel chair to which two separately operated leg rests were attached that, when not in use, hung down on either side of the chair front. When either leg rest was in use, it could be raised to a horizontal position at the level of the chair seat and thus afford support for a disabled leg when extended. When so elevated, the leg rest could be held stationary in the desired position by a ratchet, or notched locking device, on the under side. The function of the locking device was described by the defendant's medical director as "a safety measure on it so that, if undue pressure is placed upon that leg rest, with the vertical leg rest out like that, it will go down. The reason for that is, if you don't have a safety valve release, and you put undue pressure on it way out like that, you would throw the whole thing clear way forward."

Immediately before the accident in the defendant hospital, the plaintiff was seated in a wheel chair of the type described. Her left leg was flexed so that her left foot rested on a lower cross piece that served as a foot support. Her disabled right leg was extended and rested on the right leg rest, then elevated to a position almost horizontal with the chair seat. According to her testimony, which stands uncontradicted, the plaintiff, in an effort to alter the position of her body as a means of gaining a more comfortable posture, raised herself slightly by pressing down on the arms of the chair and by exerting slight pressure on her left foot. As she did so, the right leg rest "went down" tipping the chair forward slightly and causing her right foot to strike the floor in such a manner as to break the bone again at the right hip socket and to dislodge from its imbedded position the surgical nail that had been inserted to hold the fractured femur in place.

We are required, said the Court of Appeals, to consider the evidence in the aspect most favorable to the plaintiff and to accord to her the benefit of every favorable inference that can reasonably be drawn from it. We cannot, therefore, agree with the appellate division that ". . . the plaintiff failed to prove facts from which the jury could find any actionable negligence on the part of the defendant hospital." In addition to evidence to which reference has been made, there was testimony by the plaintiff's husband that while he was in his wife's hospital room on the night before her injury, he noticed a wheel chair near her bed and, while examining it casually, he observed that, when he "took hold" of the right leg rest and "set it in on a notch and pressed on it," it would "snap down" with very little pressure and that the left leg rest held better. Although the plaintiff was lying in her bed when her husband was "fussing" with the wheel chair, as she termed it, and although the chair was the one involved in the accident that befell her the next day, there is no evidence that before the accident she was informed or had reason to know that the right leg rest when elevated would drop down under light pressure. In fact, there is no evidence that at the time the right leg rest dropped down the plaintiff had exerted upon it even slight pressure.

As a patient, said the Court of Appeals, the plaintiff could rightfully expect from the defendant hospital the exercise of reasonable care in the selection and maintenance of equipment furnished for her use. Such standard of reasonable care required of the defendant that the wheel chair provided for plaintiff would be in a safe condition—as to structure and maintenance—for the use to which it was to be put. On the record before us, said the Court of Appeals, the decisive question was whether there was any substantial evidence that the proximate cause of plaintiff's injuries was a failure by the defendant properly to perform the administrative act mentioned above. We think, the court concluded, that there was such evidence which presented a question of fact for determination by a jury.

Accordingly the judgment in favor of the defendant hospital was reversed and the cause was remanded for a new trial. *Holtfoth v. Rochester General Hospital, 105 N. E. (2d) 610 (New York 1952).*

Indemnity Insurance: Extent of Coverage of Malpractice Insurance Policy.—This was an action for a declaratory judgment to determine the obligation of the plaintiff insurance company to one of its policy holders. The trial court held that no obligation under the policy existed, but this finding was reversed by the court of appeals. The company then appealed to the Supreme Court of Ohio.

A Mrs. Hirssig commenced an action against Michota, a chiropodist, to recover damages for personal injuries attributed to his negligence. She alleged that she was a patient of Michota and went to his office to receive treatment for a foot ailment; that she entered one of the treatment rooms and, following his instructions, attempted to seat herself in a metal hydraulic chair designed for the occupancy of patients; and that, after she placed her left foot on the chair and attempted to raise herself into it as she had done on previous occasions, the chair suddenly rotated to the left, causing her to lose her balance and fall to the floor, whereby she was injured. It was charged that Michota was negligent in failing to "lock" the chair before directing Mrs. Hirssig to get into it, in failing to give warning that the chair was unlocked and would rotate if stepped upon, and in failing to maintain the chair in a safe condition for use by patients.

Michota held a policy of liability insurance in the American Policyholders Insurance Company, which provided that the company would defend each claim and suit "arising out of the practice of the insured's profession as specified herein, and to pay the expenses incurred in the defense of such claim or suit in addition to the applicable limit of liability of the policy." It also provided that the insurance company would pay on behalf of the insured all sums that the insured becomes obligated to pay because of injuries resulting from professional services rendered or that should have been rendered. The insurance company contended that, under the policy, its liability either "to defend" or "to pay" was strictly limited to those injuries that might arise out of the actual rendition of professional services by the insured and that the allegations of the petition in the case of Hirssig v. Michota did not disclose an incident within the protection of the policy. Michota, on the other hand, contended that the language of the policy is in broad and comprehensive terms, and that, in conformity with the well-established and universally recognized rule, any doubt or ambiguity with respect to the meaning of the phraseology employed in the policy must be resolved in favor of the insured and against the insurer, which prepared and issued the policy and collected a premium therefor, and, further, that the injury described by Mrs. Hirssig in her petition did bring the case within the policy provisions.

This court, said the Supreme Court, is of the opinion that the insurance company is liable under its policy. The policy is entitled "Professional Liability Policy" and nowhere in the language relied on is the liability of the insurer restricted to "malpractice" or, by the wording of the policy, is liability thereunder confined to a failure on the part of the insured to exercise that standard of professional skill in the treatment of patients prescribed by law. When Mrs. Hirssig entered Michota's office and in a treatment room thereof began to follow his precise instructions in preparing herself for his professional ministrations, the relationship of patient and physician was clearly established. Her claimed injuries, according to the allegations of her petition, were due to the negligence of the chiropodist in failing to maintain apparatus employed by him in the practice of chiropody in a safe condition for her use as a patient. The injury described was one "arising out of the practice of the insured's profession." Maintaining the treatment chair in a proper and safe condition for the accommodation of patients was a service or duty directly connected with the practice by Michota of his profession as a chiropodist. The insurer, concluded the Supreme Court, is therefore obligated to defend the action of Mrs. Hirssig against Michota and, in the event of a verdict and final judgment against him, the insurer is liable to pay, on the doctor's behalf, such sum as may be within the limits of the policy. The judgment of the court of appeals against the plaintiff insurance company was therefore affirmed. *American Policyholders Insurance Company v. Michota, 103 N.E. (2d) 817 (Ohio, 1952).*

Neurotoxicity of Streptomycin Group of Drugs.—Winston presents clinical and investigative data on cochlear and vestibular complications resulting from streptomycin and dihydrostreptomycin therapy. Damage to the cochlear and vestibular mechanisms caused by the streptomycin group of drugs is always bilateral, and the deafness is of the perceptive type. Streptomycin frequently damages the vestibular apparatus and rarely damages the cochlear apparatus, while dihydrostreptomycin frequently causes deafness as well as severe damage to the vestibular apparatus. The incidence of these complications is directly proportional to the size of the daily dose of the drug and to the number of days it is administered. With streptomycin, deafness is usually preceded by tinnitus as a warning symptom. It practically never occurs with daily doses of less than 3 gm. Deafness and vestibular damage are more abrupt with dihydrostreptomycin, and these complications may become severer or be entirely delayed for some time after therapy has been discontinued. If the complications are slight or moderate, the hearing impairment and vestibular dysfunction may ultimately improve. Audiometry and vestibular turning tests should be carried out from time to time during therapy and again within six months after therapy has been discontinued. While streptomycin appears to have a much more frequent neurotoxic effect upon immature rats than adult rats and while it has been shown to cross the placenta, no neurotoxic effect upon the fetus has thus far been noted. Pregnancy, apparently, does not contraindicate the use of streptomycin. In Ménière's disease streptomycin does not eliminate the recurrent attacks of vertigo, but renders them much less severe. Because it attacks the central vestibular mechanism and possibly other brain structures as well, streptomycin should not be used for this purpose.

Limitations in Use of Gamma Globulin in Poliomyelitis.—Hammon points out serious limitations to the use of gamma globulin in prophylaxis of poliomyelitis. These are due in part to the fact that gamma globulin is an immunizing agent giving only temporary, passive protection. More important are the difficulties presented by the disease itself. Only 1 of 100 or more infections with poliomyelitis virus is clinically recognized. Undiagnosed, primary infection leads to multiple secondary infections among which may be one with clinical manifestations permitting diagnosis. This epidemiological concept leads to what may actually be the most effective use of gamma globulin: It should be used in the family at the time of exposure of the family members. When this occurs through inapparent infection, it cannot be recognized, but the primary infection in the family must frequently be manifested as an undiagnosed case. The severer a poliomyelitis epidemic becomes, the higher will be the proportion of undiagnosed, febrile illnesses that are actually poliomyelitis. Injection of family members at this time should be prior to the onset of approximately 75% of all secondary cases, *as in measles.* Expecting modification of the involvement in the earliest cases and prevention of most of the later ones, use of gamma globulin in such families should give excellent results. Epidemiological and immunologic evidence *strongly supports the* hypothesis that this is a more selective method of administra-

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

tion than indiscriminate and essentially simultaneous mass immunization of all children in all epidemic communities. The more selective approach to families, based on diagnosis or suspect diagnosis by a physician, could be handled largely by physicians in private practice with referral of others to a health department clinic. Indiscriminate, mass community injection would include not only the same children wastefully injected under the suspect case contact method because the wrong index diagnosis had been made but also all other children in all families in which not even a suspect illness occurred and would include many families in which known and suspect cases had occurred weeks before and had probably left the family solidly immune. Lack of direct, experimental evidence should not restrict administrative practice from doing what epidemiological and immunologic evidence strongly suggests is reasonable.

Sarcoidosis in Armed Forces.—The occurrence of sarcoidosis is reported in 17 members of the United States Army in Europe. White exceeded Negro patients in a ratio of 9 to 8. Presenting symptoms were chest pain in four patients and hilar adenopathy, with or without pulmonary infiltration in five. Chills, fever, anorexia, nausea and vomiting, sore throat, edema of legs were observed occasionally. Exclusive of the usual lymphadenopathy, there was a small number of physical findings, such as swollen painful joints, edema of legs, and enlargement of liver and spleen. No patient had uveoparotid, skin and bone involvement. Sarcoidosis is recognized as a generalized reaction to some unknown stimulus. The complicating factor of many known stimuli showing the same pathological response makes its diagnosis complex. Involvement cannot be determined clinically on history and physical examination, since there may be no symptoms referable to the organ and no enlargement or tenderness, although biopsy may show pronounced involvement. Liver needle biopsy, which propably provides representative evidence of sarcoidosis and is relatively harmless, was made in 15 patients and yielded positive results in 11, which again emphasized the frequent early involvement of this organ. Liver function tests showed rather poor coordination with positive biopsy results. Persistently abnormal laboratory evidence should be followed by repeated biopsies, especially if there is a consistently positive and rising sulfobromophthalein (Bromsulphalein) retention. The variability of the course of sarcoidosis and poor response to most therapeutic agents cloud its prognosis and treatment.

Pregnancy and Subacute Bacterial Endocarditis.—Questionnaires were sent to 300 hospitals, each with 2,000 or more deliveries per year. Replies received from 102 revealed a total of 113 cases of subacute bacterial endocarditis preceding or complicating pregnancy. In addition, seven case reports were collected from the British literature. The report is based on 120 cases, 85 with healed subacute bacterial endocarditis and 35 complicated by and cured of this disease during pregnancy. The maternal mortality for the series was 6.6%. Pregnancy following healed subacute bacterial endocarditis is contraindicated for the first six months following the clinical cure. During this period, lack of stabilization of the cardiac reserve results in an increased incidence of congestive failure and an increased maternal mortality rate. If pregnancy occurs during this phase, therapeutic abortion without tubal ligation is indicated during the first trimester. The advisability of childbearing is determined by a critical evaluation of the underlying cardiac lesion in cases in which subacute bacterial endocarditis has been cured for periods longer than six months. The incidence of recurrence during pregnancy is similar to that noted in the healed, nonpregnant person. The treatment of subacute bacterial endocarditis is as successful in the pregnant as in the nonpregnant patient. Early diagnosis is the key to successful treatment. The prenatal care and conduct of labor are similar to those in any patient with heart disease. Cesarean section should be performed only for obstetric indications. Routine intrapartum and postpartum use of antibiotics is advocated to prevent the recurrence of the disease.

Differential Diagnosis of Carcinoma in Situ.—There is agreement that cervical carcinoma passes through an intraepithelial phase before it begins to invade the stroma. The morphological characteristics of carcinoma in situ include marked anaplasia, hyperchromatism, polynucleosis, disparity in the size, shape, and staining quality of the nuclei, disturbance in the nuclear-protoplasmic ratio, increased mitotic activity, abnormal mitotic figures, loss of polarity, loss of layering and disorderly arrangement, and an intact basement membrane. With apparently so clear-cut a picture, it might be expected that this entity would offer little difficulty. In practice, however, there is considerable confusion as to the proper application of the term "carcinoma in situ" and consequent uncertainty as to the management of lesions so designated. This is largely attributable to the facts that the epithelium rarely fulfills all the cytological criteria and the lesions have been seen to regress or at least not to progress to invasive state, though untreated. The authors summarize observations on 4,152 cervical biopsy specimens obtained between 1930 and 1946. This number included nine invasive carcinomas with previous biopsy specimens, among which one true intraepithelial carcinoma was found. The findings among 4,187 cervical biopsy specimens obtained between 1946 and 1952 are presented, with particular emphasis on six cases diagnosed "carcinoma in situ" and followed by repeat cervical biopsies without treatment other than the repeat biopsies, which, to date, showed the lesions to be reversible. The desirability of a policy of watchful waiting in the doubtful case, particularly if the patient is young, and the comparative safety of such a policy are stressed. The "in situ" problem is likely to continue to plague the gynecologist. Findings among more than 8,000 cervical biopsy specimens support the conservative point of view, which maintains that true intraepithelial carcinoma is an exceptional finding with the limited diagnostic facilities at our disposal today. It is hoped that future research will make it possible to recognize beginning cervical carcinoma with certainty and to distinguish it from the benign carcinomimetic lesions that cause considerable confusion.

*Histoplasmin and Coccidioidin Testing in Philippine Tuberculosis Hospital. C. Halde and A. C. Reyes.—p. 655.

Testing with Histoplasmin and Coccidioidin in a Philippine Tuberculosis Hospital.—Studies were made on 824 patients in a tuberculosis hospital in the Manila area. Most histoplasmin surveys have been made along with tuberculin surveys. Since most of the Filipino patients on whom this study was conducted had demonstrable acid-fast bacilli in their sputums, tuberculin testing was not done. None of the 824 patients showed a reaction to coccidioidin, but 26 patients (3.15%) had a reaction to histoplasmin. Each reacting patient was retested two or three times and gave a consistent reaction. In the endemic areas for coccidioidomycosis in California, progressive coccidioidal granuloma with a high mortality rate has been found to develop in some Filipinos. Therefore, the absence of reactors to coccidioidin in this survey indicates that coccidioidomycosis is probably not present in the Philippines.

Streptomycin and Dihydrostreptomycin in Pulmonary Tuberculosis.—A cooperative study for a controlled clinical appraisal of streptomycin and dihydrostreptomycin in the treatment of tuberculosis was carried out in eight hospitals. Of 294 patients with pulmonary tuberculosis who were treated in hospitals in Minnesota, North Carolina, Illinois and California, according to the plan, 145 were given streptomycin and 149 dihydrostreptomycin. One gram of streptomycin or dihydrostreptomycin in a single daily intramuscular injection plus 12 gm. of *p*-aminosalicylic acid was given orally in divided doses. The standard duration of treatment was 120 consecutive days plus or minus one week. Follow-up observations were continued for a minimum of six months. Results showed that both streptomycin and dihydrostreptomycin are valuable agents in the chemotherapy of amenable forms of tuberculosis in properly selected patients. It was not possible to determine any significant difference in the therapeutic efficacy of the two drugs. When administered in combination with *p*-aminosalicylic acid, neither type of streptomycin was associated with the emergence of a significant incidence of drug-resistant infection. Vestibular toxicity, which generally occurred relatively early in the course of treatment, was more frequently observed with streptomycin. Auditory toxicity, which tended to occur relatively later, was more frequently due to dihydrostreptomycin. Although usually ranging from subclinical to moderate in degree, the auditory disturbance can be of serious proportions. It can be progressive or it may appear belatedly after chemotherapy has ceased. High tone (audiometric) loss or complaint of sustained high-pitched tinnitus is the first indication of side-effects and should always be considered significant. Allergic responses to streptomycin were not infrequent and were occasionally severe. Allergic reactions were rarely observed when dihydrostreptomycin was employed.

Comparative Study of Streptomycin and Dihydrostreptomycin.—Of 141 patients with pulmonary tuberculosis admitted to four New York State tuberculosis hospitals which participated in the cooperative study reported in the same issue of this journal, 73 received dihydrostreptomycin and 68 streptomycin. The dosage of streptomycin or dihydrostreptomycin was 20 mg. per kilogram of body weight per day, rather than the 1 gm. dose per day used in the other four hospitals. The patients also were given 12 gm. of *p*-aminosalicylic acid orally daily. A small number of patients received only the basic 120 consecutive days of chemotherapy (±7 days), and the vast majority received drug therapy for longer periods. No difference in the therapeutic efficacy of streptomycin and dihydrostreptomycin was discernible when they were administered for 120 days and when the results were evaluated at that time. No significant difference was observed in the frequency of emergence of drug-resistant strains, which with either drug was less than 8%. The small percentage of patients in each original group who were still sputum positive after one year of treatment emphasizes the impropriety of drawing conclusions about the drug resistance studies with respect to the two drugs. Ototoxicity of the two drugs is of considerable importance. Vestibular disturbances occurred with either drug, but were more frequent, of greater severity, and often of earlier occurrence with streptomycin. Auditory disturbances were relatively uncommon with streptomycin and, when present, were usually less severe. Auditory disturbances are more to be expected when dihydrostreptomycin is used. They were usually mild or slight in severity when the drug was given for only 120 days. They were of greater severity and frequency when administration was prolonged beyond six months of daily treatment. The auditory disturbances occasionally progressed even after therapy was stopped, or they appeared some time after the conclusion of chemotherapy. The earliest changes of ototoxicity detected with either drug were usually tinnitus and/or high-tone loss of relatively mild degree.

Intralobar Pulmonary Sequestration.—Six cases of a congenital lung anomaly of teratological and clinical interest are reported in three boys and three girls. The anomaly consists of a portion of a displaced lung tissue in the chest cavity with hypoplastic alveoli and dilated bronchi that give the lung its honeycombed or cystic appearance. This displaced lung is the recipient of a systemic vascular supply usually from the aorta. It has been referred to as intralobar sequestration since Price's paper on the first case of this type diagnosed at operation in 1948. Of the author's six cases some were diagnosed preoperatively and the others by examination of the specimen after excision and by the finding of an aberrant artery when the portion of the lung was removed. The condition is probably due to the amputation of a primordial lung bud by an aberrant artery occurring in the 4 to 14 mm. embryo. Clinical findings consisted of cough with little or no sputum and recurrent bouts of fever and were occasionally accompanied by hemoptysis. The radiographic changes demonstrating the true nature of the case are a mass often of considerable density, *at times homogenous and cystic areas usually visualized in* it or in nearby portions of the lung. The mediastinum is in the midline. The bronchogram usually shows a mass into which the opaque contrast medium does not penetrate; occasionally it may enter for a short distance. The demonstration of a complete bronchial tree, diseased or otherwise, extraneous to the mass, is important. Attention to this detail will prevent removal of a mass and leaving behind bronchiectatic portions of the lung with the false assumption that a complete excision was made. The only effective therapy is surgical removal of the abnormal lung and any infected normally developed lung. Three cases are cited in which the whole lung was involved in the process. The question was raised whether such a result could not ensue rather than agenesis when earlier more massive portions of the bronchial tree are amputated in the embryo.

Cavitation Within Bland Pulmonary Infarcts.—Of 100 cases of pulmonary infarction reviewed by the author, the occurrence of pulmonary infarction due to bland emboli showing roentgenologic evidence of pulmonary cavitation is reported in four men and one woman between the ages of 26 and 64. It was established that cavitation within a pulmonary infarct might occur in the absence of pyogenic abscess formation. This phenomenon of aseptic necrosis with cavity formation is unusual and is significant only in that it should be recognized as one of the sequelae of pulmonary infarction. Mere presence of pulmonary cavitation did not seem to be a grave prognostic sign. Antibiotic therapy apparently controls infection sufficiently so that these necrotic infarcts may heal without surgical treatment. The diagnosis of pulmonary infarction could be made much more frequently by relying on the recognized clinical and roentgenological signs of the condition.

Recontamination of Washed Bedding in Laundries.—Church and Loosli describe bacteriological studies that were carried out in two laundries (one hospital and one commercial). The air, wash and rinse waters, and textiles before washing and after rinsing and ironing were examined to determine the source of organisms found in the laundered materials. It was found that the laundry processes were efficient in removing bacteria from the fabrics during washing but that the materials became recontaminated during water extraction in the spin dryer or while hanging in the laundry to dry. This was shown by the fact that the air, during the sorting of linen and other activities, became highly contaminated with bacteria that settled out on woolen blankets hanging in the laundry and on fabrics at the folding table. In addition, large numbers of air-borne bacteria were drawn through the spin dryers during the process of water extraction and impinged on the washed textiles. Although the ironing process killed large numbers of these organisms, many survived. The surviving organisms were mainly nonhemolytic alpha streptococci and Micrococcus albus and aureus, which are potential human pathogens. It is not inconceivable that so-called "clean linen," which has become recontaminated with air-borne organisms dispersed from unwashed bedding, may be the source of initiating serious infections when placed again on hospital beds. The authors discuss measures to prevent the recontamination of washed bedding.

Multivalvular Heart Disease and Simultaneous Surgical Correction.—Bolton and associates operated on 843 lesions of the mitral valve and on 74 patients with aortic stenosis. The 74 patients with aortic lesions included 28 with associated mitral valvular lesions that were treated concomitantly. The authors discuss the techniques utilized for mitral insufficiency, such as mitral commissurorrhaphy or valvular suturing. In some cases of mitral valvular disease, stenosis and insufficiency are associated. In such instances the commissurotomy is done first. The regurgitation may diminish owing to this valvular mobilization to such a point that valvular suturing is not necessary. This is determined by palpating the regurgitant jet that strikes the finger in the left atrium during each ventricular systole. In the estimation of these authors 12 to 15 cc. per heartbeat is the upper limit of regurgitation that can be readily tolerated. When necessary, the valvular suturing is carried out after commissurotomy. The early attempts at aortic commissurotomy consisted of inserting a dilator through the wall of the left ventricle and advancing the instrument to the level of the aortic valvular ring. The dilator was then expanded in order to dilate the valvular orifice. The dilating mechanism was one which expanded in an elliptic form. There was a tendency for the dilated portion to slip out of the valvular orifice, which resulted in an inadequate dilation. This instrument was abandoned when the Bailey aortic dilator was developed, which proved to be very satisfactory. When there is coexisting mitral valvular and aortic valvular disease, the problem of which lesion should be treated first is baffling. If there is mitral obstruction present and this is relieved, the persistence of aortic obstruction will probably result in left ventricular engorgement if the aortic obstruction is not relieved in short order. The authors generally do the mitral operation first. If one's experience in the treatment of aortic stenosis is somewhat limited, it might be wise to perform the aortic commissurotomy first. Then, if it becomes necessary to abandon further operation at this time, the mitral procedure can be performed at a later date. The authors state that of the 28 patients subjected to concomitant treatment of multivalvular heart disease 6 died. Of the 22 survivors, 20 were improved.

Percutaneous Femoral Artery Aortography for Evaluation of Retroperitoneal Masses.—Evaluation of retroperitoneal masses is frequently difficult. Arteriography, venography, and retroperitoneal oxygen injection can increase information about such masses. Arteriography is the most important of these, and can be done either by direct translumbar puncture of the aorta or by various catheterization methods of introducing radiopaque dye into the abdominal portion of the aorta. These methods of catheterization utilize surgical cut-down on the femoral artery, which is not only difficult and time consuming but also involves danger of thrombosis of the femoral artery. Peirce used the percutaneous femoral artery approach to catheterize the abdominal portion of the aorta, thus making practical a simple, accurate, and versatile second method of abdominal aortographic investigation. The method allows accurate injection of a contrast medium with the patient in any position. It is fairly readily learned and is economical of personnel and equipment.

Diagnosis of Intracranial Mass Lesions.—The relative accuracy of electroencephalography, pneumoencephalography, ventriculography, and angiography as aids in diagnosis of verified, selected intracranial mass lesions was studied in 200 consecutive patients. No single method proved adequate in the localization of all types of intracranial mass lesions. Of the 224 preoperative electroencephalograms, which were recorded in 198 patients, 168 were abnormal. The diagnosis was aided by the electroencephalogram in 101 cases, the tracing indicating the site or cranial fossa of involvement; but encephalography can be considered only as a useful adjunct to other diagnostic methods. Projected electroencephalographic abnormalities may be falsely interpreted as focal abnormalities, and focal abnormalities tend to become generalized with progression of the disease. Of the 90 pneumoencephalograms performed by the removal of the cerebrospinal fluid and replacement with room air through the lumbar route, employed in the diagnosis of 82 cases, 46 were recorded as abnormal. Thirty of the tumors were localized by this method, an accuracy of 36%. Pneumoencephalography is valuable in the localization of hemispheric mass lesions and is the procedure of choice with tumors at the midline base. Of the 100 ventriculograms performed by the replacement of ventricular fluid with room air through two burr openings in the cranium on 96 patients, 4 were diagnostic failures because of insufficient ventricular filling. In 88 the findings were abnormal, and in 86 they were diagnostic. Ventriculography is the most useful method in the localization of any intracranial mass lesion; it has a general accuracy of 90%. It is the only method, with the exception of vertebral angiography, that is helpful in the diagnosis of posterior fossa masses. Fifty-seven carotid angiograms were performed on 57 patients. Of the 57 masses, 31 were localized exactly. Masses of the anterior two-thirds of the hemispheres and about 50% of those at the midline base may be localized by carotid angiography.

Treatment of Aneurysms of the Circle of Willis.—The results of operations for bleeding aneurysms of the circle of Willis depend on the time in relation to bleeding at which surgical intervention is performed. Of 15 patients operated on in the acute stage between a few hours up to 22 days after the onset of subarachnoid hemorrhage caused by saccular aneurysms of the circle of Willis, 8 died. Good recoveries followed in six patients, and in one patient hemiplegia began to develop the day after operation and became permanent. The procedure employed was ligature of the neck of the aneurysm in 12 patients, wrapping the aneurysm with muscle in 1, and trapping of the aneurysm in 2. In five of the eight fatal cases pronounced vasospasm was present. The authors' impressions from these experiences are that, when massive hemorrhage has occurred, no operation is likely to save the patient, that as a rule it is useless to operate unless the patient survives the first two days, and that the circulation of the brain is profoundly disturbed during the first two or three weeks following hemorrhage, this disturbance being the result both of the increase in intracranial pressure and the vasoconstriction almost invariably present in these cases. During the first three weeks after hemorrhage the results of all types of operations are about the same as with conservative treatment. To the credit side of the surgical intervention must be added that, if the neck of the aneurysm has been clipped, the patient is protected against further hemorrhage. If early operation is performed, efforts must be made to overcome the vasospasm. Of 63 patients with saccular aneurysms of the circle of Willis operated on during the quiescent period following the acute stage, 2 died. The procedure employed was ligature of the neck of the aneurysm, usually with a clip, in 48 patients, wrapping the aneurysm with muscle in 8, trapping the aneurysm in 2, and exploration in 5. Operations after the patient has recovered from the initial hemorrhage are to be considered as a prophylactic measure aimed at preventing further hemorrhage. Clipping of the neck of the aneurysm or trapping meets the conditions stipulated for operations performed after the patient's recovery from the initial hemorrhage. Mortality and morbidity after clipping of the neck of the aneurysm, performed three to four weeks after the last attack of bleeding, is very low and protection against future hemorrhage is excellent.

Lobectomy in Lobar Obstructive Emphysema in Infancy.—Severe obstructive emphysema, most marked in a single lobe, was observed in four infants. In two the left upper lobe was involved; in two, the right middle lobe. Lobectomy was performed successfully in each of the infants; the youngest was 6 days old and the oldest 8 months. The removed lobes showed marked, generalized emphysema. Infection was not present, and no bronchial obstruction was found. It is believed that the obstructive emphysema was due to a check valve mechanism produced by abnormal flaccidity of the bronchi. Each of the infants was improved by lobectomy. All, however, had respiratory symptoms following discharge. In two of the infants there was roentgenographic evidence following operation of emphysema in other portions of the lungs. The bronchial abnormality probably involved other portions of the bronchial tree. Sloan reviews reports on this type of emphysema and stresses that the infants observed at his clinic had labored respirations, wheezing cough, and cyanosis. The symptoms were usually believed to be related to a respiratory infection, but none of the infants had such an infection when examined. The use of antibiotics did not produce improvement. On physical examination there was hyperresonance to percussion over the involved hemithorax, with diminution of breath sounds on auscultation. An expiratory wheeze was often present when the infants cried. The emphysematous lobe filled the entire hemithorax. There was compression of adjacent lung tissue. The mediastinum was shifted to the opposite side. The hemidiaphragm on the affected side was depressed. Shift of the mediastinum with respiration could be demonstrated in two of the infants. In none of the infants was there clinical or roentgenographic evidence of regression of the emphysema prior to operation, and in two of the infants progression of the emphysema occurred. In each case there had been confusion about the diagnosis. Most frequently it was thought that the infant had a large pulmonary cyst. On other occasions, it was felt that atelectasis or pneumonitis was present in the compressed lobes and that the emphysema was compensatory. In one infant a diagnosis of massive collapse of the opposite lung was made. Two of the infants were bronchoscoped prior to operation. The only abnormality noted was a tendency for the bronchi to collapse during expiration. No attempt was made in these infants to decompress the emphysematous lobe by thoracentesis prior to operation. Such an attempt would appear to be inadvisable.

Aortic Commissurotomy.—Larzelere and Bailey review the etiology and pathogenesis of aortic stenosis and point out that just as mitral stenosis can be corrected by instrumental and/or digital means, so can a stenosed aortic orifice be opened. The presence of three cusps in the aortic valve would mechanically provide even more assurance that an unfavorable insufficiency would not result from commissurotomy. The present mode of treatment and the instrument that will accomplish safe and adequate aortic commissurotomy are described. The instrument is the Bailey aortic dilator, which is a triradiate parallel expanding mechanism, containing three flanged blades. It is used to part the fused aortic commissures. A transventricular approach is used; the instrument is passed into place over a previously inserted beaded guide wire. The authors present observations on 42 patients in whom aortic commissurotomy was done. This number included 25 patients with significant mitral stenosis; 23 mitral commissurotomies were performed. Two of the 23 underwent simultaneous mitral commissurorrhaphy (commissural suturing) for significant associated insufficiency. Also, in the three cases of aortic stenosis associated with a significant degree of mitral insufficiency, two commissurorrhaphies of the mitral valve were performed. In one case of aortic insufficiency associated with slight degrees of aortic stenosis and mitral insufficiency, an aortic commissurotomy and a transaortic Nylon graft tamponage of the aortic valve were performed, along with mitral valve exploration. There were seven deaths in the 42 cases. One death occurred in the 13 patients with isolated aortic stenosis and was due to ventricular fibrillation. There were three deaths in 19 patients who had both aortic and mitral stenosis, and in 17 in whom both mitral and aortic commissurotomies were done. One of these was due to bleeding from the ventricular surgical wound; one resulted from a massive pulmonary embolism due to thrombosis of the right auricular appendage; and one resulted from recurrent pulmonary edema following mitral insufficiency produced at surgery. In five cases of aortic stenosis, mitral stenosis, and mitral insufficiency (each lesion significant), there were two deaths. One of these occurred on the operating table and was due to a tear in the hemostatic ventricular purse-string suture. The other death, 28 days postoperatively, was due to reactivation of rheumatic infection with pericarditis, congestive failure, and perhaps some induced aortic insufficiency. In three cases of aortic stenosis and mitral insufficiency (three aortic commissurotomies and two mitral commissurorrhaphies), there was one death caused by pulmonary edema probably resulting from a too tightly sutured mitral valve. The authors hope that aortic commissurotomy for aortic stenosis will prove to be as beneficial as mitral commissurotomy for mitral stenosis.

Hydrocortisone (Compound F) by Local Injection in Arthritis.—Ramsey and Key present their observations on 119 patients with arthritis who received a total of 218 local injections of hydrocortisone. These patients had not received adrenal steroids by any other route, and they were observed for a sufficient period of time to permit evaluation of the results. The injections were given after 1% procaine had been injected into the skin and along the path of the needle but not into the joint, if this could be avoided. The hydrocortisone was then injected into the joint with another needle and syringe. The dose of hydrocortisone was from 25 to 50 mg. for the major joints and 5 to 20 mg. for the smaller joints. A total of 100 injections was given into 57 joints of 51 patients with hypertrophic arthritis. The response was considered satisfactory if there was at least a 50% relief in symptoms for a minimum of a week. With this criterion, 48 of 57 joints showed a satisfactory response. Many of these patients experienced nearly complete relief of symptoms for from 3 to 10 weeks or longer. In 14 patients with active rheumatoid arthritis 20 of 22 involved joints showed some response to intra-articular injections of hydrocortisone, but in general the response in these patients was of shorter duration than was the case in patients with hypertrophic arthritis. Thirty-three patients were given a total of 52 injections into painful bursas, with curative effect in 17 (mostly acute calcific bursitis of shoulder), partial relief in 9, and no benefit in 7. Tennis elbow, painful heels, acutely inflamed bunions and hemarthrosis of the knee following meniscectomy were some of the other conditions in which hydrocortisone was administered by local injection. No serious complications were observed in these patients, but the possibility of producing a septic arthritis by contamination should be kept in mind, and a careful injection technique should be used. The authors resorted to intra-articular injection only in selected cases with relatively severe symptoms, because they feel that a needle should not be introduced into a joint without good reason. While the treatment is not a panacea, it is a valuable therapeutic agent not only for acutely painful arthritic joints but also for its local anti-inflammatory action in several other painful conditions in which the etiology is obscure.

Progressive Systemic Sclerosis (Scleroderma).—Beigelman and associates present observations on 15 patients with scleroderma, and suggest that the term progressive systemic sclerosis more accurately reflects the diffuse nature of the disease, which is not limited to the skin. Constitutional symptoms were present in all of the 15 cases. Twelve had lost weight, about half of the patients had noticed weakness or increased fatigability, and 6 had elevated temperatures. Twelve patients had typical Raynaud's syndrome. Joint pains or swelling or stiffness, or all three were present in 12 patients at some time during the course of their illness. Fourteen patients had cardiorespiratory embarrassment. Nine complained of dyspnea, and seven had ankle edema. Six patients had palpitations. Three were hoarse, without laryngeal infection. Eleven had complaints referable to the gastrointestinal system. Eight noted dysphagia. The earliest symptom in seven cases was referable to the joints rather than the skin. Of those who had skin manifestations as the first sign of disease some noted thickening of the skin first, whereas others had pruritus, erythema, vitiligo and, in one case, felons. Roentgenograms were studied in nine cases. Common findings included pulmonary fibrotic streaks and nodules, cardiac changes, and esophageal abnormalities. Soft-tissue, bone, and joint lesions were frequent. Four patients had calcinosis. Electrocardiographic changes were frequent and arrhythmias were the most prominent. All autopsied cases demonstrated diffuse visceral fibrotic lesions. Vascular sclerosis and intimal hyperplasia were common. One case displayed inflammation of the mitral and tricuspid valves. All forms of therapy, including corticotropin and cortisone in most cases, proved ineffective. The histological findings in the present series, which confirm primary and basic involvement of connective tissue, place this disease, pathogenetically, in the same group with the collagen diseases, particularly disseminated lupus erythematosus. The major difference in the clinical picture and course of the two diseases can be perhaps explained through differences in the intensity and diffuseness of the reaction. Acute disseminated lupus suggests a comparatively severe, rapid connective tissue reaction, with edema and necrosis predominating, and progressive systemic sclerosis (scleroderma) represents a slow, torpid, generalized mesenchymal response, with fibrosis and sclerosis predominating. The ubiquitous proliferative hyaline vascular lesions observed in this series were probably sequelae of early, mild vessel-wall reaction preceding mesenchymal involvement.

Current Status of Acute Rheumatic Fever in State of Washington. R. A. Bruce.—p. 636.

Mitral Commissurotomy.—Merendino and co-workers select patients for commissurotomy on the basis of the physical fitness index, which is derived from performance while walking on a treadmill at 1.7 miles per hour on a 10% grade for 10 minutes. The patient is not permitted to walk either faster or slower; he must either walk or stop. Endurance is measured by the number of minutes he is able to walk. Information is obtained simultaneously by means of a face mask connected to a Beckman oxygen analyzer, which continuously records the amount of oxygen extracted from the atmosphere. The third factor utilized in computation of the physical fitness index is the total number of heart beats in the first three minutes following the termination of exercise, regardless of its duration. The formula of the physical fitness index is given. Commissurotomy was regarded as indicated: (1) in patients with mitral stenosis without serious left ventricular enlargement who are disabled by the disease; (2) in women with mitral stenosis in the childbearing age who have had heart failure with a previous pregnancy; and (3) in patients with rheumatic heart disease and left auricular enlargement who have exhibited one or more episodes of peripheral embolism. Fifteen patients with disabling mitral stenosis were operated on. An additional patient, a girl of 19, who was in severe cardiac failure during her last pregnancy, was subjected to prophylactic mitral commissurotomy, although following pregnancy she was not disabled in any way. In another patient, the mitral valve was explored; because of serious mitral regurgitation and the feeling of the surgeon that the patient would be harmed by commissurotomy, only ablation of the auricular appendage was carried out. No deaths occurred in these 17 patients, and there was no evidence of embolism during surgery. Of eight patients with fibrillation preoperatively, most had a trial period of quinidine therapy. In only three patients in this group was a normal sinus rhythm obtained after surgery. Quinidine is still necessary to maintain normal sinus rhythm. Two patients who received digitalis for years discontinued all cardiac medication. Almost two months must elapse before objective evidence of improvement can be noted. Those followed the longest have shown the best results. Improvement has been noted to continue for one year. Many patients who felt better postoperatively did not show objective improvement. Some who felt little different revealed an impressive improvement in their physical fitness index. It is of interest that those who felt considerably better following commissurotomy but who did not show early improvement in their physical fitness index subsequently improved. One important indication of the surgical result, which most patients note immediately, is improvement in their ability to breathe or take a deep breath.

Chemotherapy of Miliary Tuberculosis and Tuberculous Meningitis.—The United States Public Health Service early in 1948 initiated a study of the use of Promizole (2-amino-5-sulfanilylthiazole) and *p*-aminosalicylic acid in combination with streptomycin for childhood miliary and meningeal tuberculosis. Two combinations of drugs were compared in a cooperative study of 32 children with acute hematogenous miliary tuberculosis treated at seven different pediatric centers under a common protocol. Eighteen children were given streptomycin intramuscularly and *p*-aminosalicylic acid and Promizole orally; 14 children were given streptomycin and *p*-aminosalicylic acid without Promizole. A one year follow-up of this small group showed no significant differences in the results from the use of Promizole. Five of 10 children treated initially with a streptomycin dose of 20 mg. per kilogram intramuscularly twice a day were either dead or had meningitis, while only 2 of 22 children treated with a 50 mg. dose died; one of these had meningitis. Twenty-six of the original 32 patients were alive 12 months after the start of treatment. Relapse of miliary disease was not encountered during the first year of this study. The optimum duration of treatment is still uncertain. The fact that three patients developed meningitis at 110, 125, and 130 days of study suggests that treatment should be relatively long. Another follow-up study, after a span of two to four years from the first day of treatment, revealed that all 26 patients were still alive. Twenty of the 24 children who had been in good condition without gross handicap or residual effects at the end of one year remained well. None of these had sequelae or relapses. The other six children, although free of miliary disease, had or were suspected of having other forms of tuberculosis. Of 93 children with tuberculous meningitis, of whom 23 also had miliary tuberculosis, half were given streptomycin intramuscularly, streptomycin intrathecally, and *p*-aminosalicylic acid and Promizole by mouth. The remainder received an identical regimen except that Promizole was omitted. Forty-two patients survived the first year; 24 of these had no serious sequelae from the disease. No differences were noted in the course of the disease among those who received Promizole and those who did not, and the one year survival rates in the two groups were practically identical. Revision of the streptomycin dosage, which took place after the study had been in progress seven months, produced results that appear to justify the change. A dose of streptomycin of 50 mg. per kilogram intramuscularly twice daily to a maximum of 1.5 gm. twice daily was apparently more effective than 20 mg. per kilogram twice daily. From two to four years after onset of treatment 54 of the 93 children with tuberculous meningitis had died, 12 were living with gross residual effects, one patient could not be traced, and 26 were alive without significant sequelae from meningitis.

Agglutination of Treponema Pallidum in Syphilitic Serums.—Numerous unsuccessful attempts have been made to demonstrate specific agglutination of pathogenic Treponema pallidum in syphilitic serum. Most such attempts have met with failure because of the tendency of the organisms to agglutinate spontaneously. Interest in the subject was revived by the report of Tani that spirochetes killed with antiformin showed no such spontaneous clumping but were agglutinated in syphilitic serum after an incubation period of 24 hours, and that organisms so treated provided satisfactory antigens for the serodiagnosis of syphilis. The agglutination technique described was devised by bringing together the findings of two separate lines of investigation. The experiments of Tani were confirmed and extended. At the same time, there was in progress a study of complement in the Treponema pallidum immobilization test. A study was made of the effects of adding fresh steer serum to mixtures of T. pallidum and syphilitic serum. Because of its content of conglutinin, the steer serum caused disappearance rather than immobilization of the spirochetes under the conditions of the T. pallidum immobilization test and greatly accelerated and enhanced the clumping of the organisms in the agglutination test. The agglutination test performed by this method appears to compare favorably both in specificity and sensitivity with the T. pallidum immobilization test.

Supraclavicular Shadows in Chest Films.—Supraclavicular shadows, present on most posteroanterior films of the chest, are pointed out as normal features, and the student is cautioned against confusing them with pathological lesions. Masses in the neck resulting from lymphomas, tuberculosis, thyroid, salivary gland, laryngeal, and superior sulcus tumors, and metastatic involvement from carcinoma of the breast and testes may partially or completely obliterate the supraclavicular fossas, either as a result of metastasis from a distant primary lesion or by direct extension. Thus tumors or other disease processes that result in obliteration of the supraclavicular fossas can be detected roentgenographically by absence of one or both of the supraclavicular shadows. Twelve cases showing abnormal supraclavicular shadows produced by disease are presented and several are illustrated. An evaluation of supraclavicular shadows should be made routinely during the interpretation of all posteroanterior films of the chest. If the shadows are present bilaterally and are normal in appearance, no comment should be made concerning them. Unilateral absence should be reported and investigated clinically, provided the film does not indicate obesity or gross malposition. Bilateral absence may be significant and should be investigated when the patient is of normal or subnormal weight.

Estrogen Excretion in Women with Breast Cancer Before and After Adrenalectomy.—Estrogen assays were performed on the urine of 12 women with breast cancer and of 12 normal women who served as controls. The urinary excretion of estrogen in premenopausal women was in the same range regardless of the presence or absence of breast cancer. Elimination of ovarian function by roentgen irradiation or ovariectomy led to lowered values of estrogen in the urine. When adrenalectomy was performed after elimination of ovarian function, estrogen was no longer detectable in the urine. Nine of 12 patients with mammary cancer subjected to adrenalectomy showed a measurable decrease in the neoplastic involvement after the operation. The author stresses that patients with breast cancer who had had eradication of ovarian function by irradiation or surgical excision still excreted estrogen in significant amount; that adrenalectomy eliminated estrogen from the urine of those cases. It is evident that the adrenals are the only significant source of estrogen in women with breast cancer who do not have active ovarian function. The three patients with mammary cancer who did not have a regression of the neoplasm after adrenalectomy, excreted preoperatively amounts of estrogen, which in two cases were below the mean titer for ovariectomized women. It is not possible to state from this study that the reduction of estrogen was the critical factor in the remission of the disease in the patients who were benefited.

After-Cough Fainting in Bronchial Asthma.—According to Derbes and Kerr, few physicians are aware that fainting after coughing is frequently a complication of bronchial asthma. Although the condition is not frequent, failure to recognize this syndrome in asthmatic patients leads to confusion, needless consultation, and undue apprehension. The syndrome of syncope following cough has been reported under such terms as laryngeal vertigo, laryngeal ictus, laryngeal apoplexy, bronchial syncope, cough syndrome, tussive syncope, posttussive syncope, and tussigenic ictus. The condition is much more frequent in men than in women, all but 9 of the 290 cases, so far reported, involving men. The authors observed 35 cases of this complication, which they described previously. The illustrative case presented here was that of a 30-year-old physician. Chest examination often discloses chronic infection. Of the authors' patients, 9 had asthma, 12 emphysema, 3 bronchiectasis, 2 pneumonoconiosis, and 1 sarcoidosis. Of 28 patients questioned regarding the use of alcohol, only 2 were abstainers. The cough is usually dry, barking, paroxysmal, and obstinate. It may be accompanied by dyspnea, congestion or asphyxia. The face is congested during the attack, and is either red or cyanotic. Although the syndrome is usually self-limited and benign, the course varies greatly. Four deaths have been reported from after-cough fainting. The attack itself requires little treatment, because it terminates quickly as a rule. Some patients who experience premonitory symptoms feel that they can abort an attack by measures such as firmly grasping an object for support, holding the breath, grasping the larynx, sucking a lozenge, spraying coccaine in the pharynx, or fanning themselves. Certain other patients having warning symptoms, but not being able to abort the attack, can place themselves in a position to minimize harming themselves in the anticipated fall. In cases associated with bronchial asthma the treatment of after-cough syncope consists of intensive treatment of the bronchial asthma.

Segmental Gastric Resection for Treatment of Peptic Ulcer.—MacLean and associates present a critical evaluation of segmental gastric resections as performed at the hospital of the University of Minnesota during the last two and one-half years. The results obtained in 90 patients treated with this method were compared with those in 953 patients, who earlier underwent Billroth 2 type gastric resections between the years of 1940 and 1949 for benign lesions of the esophagus, stomach, or duodenum. It was found that segmental gastric resection in which all but 10 to 15% of the acid-secreting area of the stomach is resected is a satisfactory operation for peptic ulcer when accompanied by pyloroplasty. Not only benign gastric and duodenal ulcer, but also esophagitis and lower esophageal stricture were treated successfully with segmental resection. In the presence of supraduodenal ulceration or a scarred and deformed duodenum, the difficulties of closure or anastomosis in this area can be avoided by utilizing segmental resection. Postprandial distress occurs early after segmental resection, but anemia and recurrent ulceration were never observed in the careful follow-up of 90 patients. Food intolerance was limited to milk, ice cream and sweets, but this was frequently encountered. Eighty-eight per cent of the patients lost weight compared to their weight five years before operation. The average weight loss was 19 lb. (8.6 kg.). Over 90% of the patients felt they were improved or greatly improved by the operation. Four patients felt they had not been helped. On the basis of technical advantages, physiological aspects, and careful postoperative evaluation, the authors consider segmental gastric resection a superior operation for the acid peptic diathesis to the Billroth 2 procedure.

Radical Gastrectomy for Benign Gastric Ulcer.—The common surgical procedure for gastric ulcer, according to Boyden, is removal of the lower two-thirds of the stomach. For the ulcer proving to be malignant such an operation is entirely inadequate. Were it possible to determine at operation which gastric ulcers are malignant, then wide excision of the lymphatic bed could be performed in those cases. But with the stomach in his hand, the surgeon cannot tell the malignant from the benign ulcer, and it is usually no more apparent to the pathologist on gross examination. Biopsy of the ulcer margin may miss the area of malignancy. Excision of the ulcer for frozen section is commonly misleading because of the difficulty of accurate interpretation by this method in this organ. Excision of the ulcer for immediate examination is often impractical because of its location or adherence to adjacent organs. Biopsy of one or two lymph nodes is inadequate. The ideal treatment of carcinoma of the stomach is total gastrectomy with excision of wide segments of the duodenum and esophagus and removal of all of the greater and lesser omenta, the gastrocolic omentum, and the spleen. Admittedly a compromise, radical subtotal gastrectomy should include all of the zones of lymphatic spread. Boyden reviewed the records of all patients operated on at the Portland Clinic for gastric ulcer and carcinoma during the 6 years from 1946 to 1952. During this interval 70 patients with gastric ulcer were operated on. Pathological examinations were made in 66 cases (eliminating 3 cases of perforated ulcer and 1 of vagotomy and gastroenterostomy). Eight of these lesions were malignant. During the same period (1946 to 1952) 74 patients were operated on in the Portland Clinic for carcinoma of the stomach. These include the 8 with malignant ulcers mentioned previously. Twenty-four lesions were inoperable. Subtotal gastrectomy was undertaken in 38 cases, total gastrectomy in 8, partial esophagogastrectomy in 4. The operative mortality in all resections was 14%. The author advocates subtotal gastrectomy for all gastric ulcers.

Streptokinase-Streptodornase in Thoracic Empyema.—Finnerty reviews the evolution of the treatment of empyema and gives particular attention to the use of streptokinase-streptodornase, which, in addition to making the purulent exudate less viscous, accomplishes several other objectives: It breaks up loculations, converts the empyema space into a single one, and thus renders it more available to the action of locally instilled antibiotics. It also obviates the necessity of needle aspirations in multiple sites. Organisms trapped in the fibrin mesh are liberated and are more liable to the action of antibiotics. The fibrin peel on the pleural surfaces is lysed, thus enabling the lung to expand and obliterate the dead space. This debridement of the pleural surfaces probably also allows the antibiotic, as well as the patient's own leukocytes and antibodies, to enter the infected area and exert their effect. The streptokinase-streptodornase is supplied in moisture-proof sterile ampuls, each ampul containing approximately 100,000 units of streptokinase and about ¼ that amount of streptodornase. About 100,000 to 200,000 units of streptokinase are diluted in 30 to 40 cc. of sterile isotonic sodium chloride solution and are injected into the empyema space. From 8 to 18 hours later thoracentesis is performed. Many patients require only one or two treatments, but some require many. The most important point is that, after injection of the enzymes, complete aspiration must be done, because the enzyme action is self-terminating and, if the lysed material is not removed, redeposition of fibrin will occur. Most failures are due to inadequate removal of liquified material or to the enzymes not having been injected into the proper area in adequate dosages. Because of this and because of the fact that patients frequently object to multiple thoracentesis, it occurred to the author that the use of antibiotics and enzymes in combination with surgical closed intercostal drainage with active suction might represent a further advance in the therapy of empyemas. The obvious advantage of this method over that just described is that constant drainage should shorten the therapy and be more comfortable for the patient and less time consuming for the physician. Accordingly, 15 patients were treated by this method. The conditions included putrid empyemas, lung abscess with large bronchopleural fistulas, and Friedländer's abscess with fistula and empyema. The method obliterated the empyema spaces and rendered more suitable for surgery those in which excision was indicated. The plan of this treatment and several case histories are presented.

of 12 patients with mammary cancer subjected to adrenalectomy showed a measurable decrease in the neoplastic involvement after the operation. The author stresses that patients with breast cancer who had had eradication of ovarian function by irradiation or surgical excision still excreted estrogen in significant amount; that adrenalectomy eliminated estrogen from the urine of those cases. It is evident that the adrenals are the only significant source of estrogen in women with breast cancer who do not have active ovarian function. The three patients with mammary cancer who did not have a regression of the neoplasm after adrenalectomy, excreted preoperatively amounts of estrogen, which in two cases were below the mean titer for ovariectomized women. It is not possible to state from this study that the reduction of estrogen was the critical factor in the remission of the disease in the patients who were benefited.

After-Cough Fainting in Bronchial Asthma.—According to Derbes and Kerr, few physicians are aware that fainting after coughing is frequently a complication of bronchial asthma. Although the condition is not frequent, failure to recognize this syndrome in asthmatic patients leads to confusion, needless consultation, and undue apprehension. The syndrome of syncope following cough has been reported under such terms as laryngeal vertigo, laryngeal ictus, laryngeal apoplexy, bronchial syncope, cough syndrome, tussive syncope, posttussive syncope, and tussigenic ictus. The condition is much more frequent in men than in women, all but 9 of the 290 cases, so far reported, involving men. The authors observed 35 cases of this complication, which they described previously. The illustrative case presented here was that of a 30-year-old physician. Chest examination often discloses chronic infection. Of the authors' patients, 9 had asthma, 12 emphysema, 3 bronchiectasis, 2 pneumonoconiosis, and 1 sarcoidosis. Of 28 patients questioned regarding the use of alcohol, only 2 were abstainers. The cough is usually dry, barking, paroxysmal, and obstinate. It may be accompanied by dyspnea, congestion or asphyxia. The face is congested during the attack, and is either red or cyanotic. Although the syndrome is usually self-limited and benign, the course varies greatly. Four deaths have been reported from after-cough fainting. The attack itself requires little treatment, because it terminates quickly as a rule. Some patients who experience premonitory symptoms feel that they can abort an attack by measures such as firmly grasping an object for support, holding the breath, grasping the larynx, sucking a lozenge, spraying coccaine in the pharynx, or fanning themselves. Certain other patients having warning symptoms, but not being able to abort the attack, can place themselves in a position to minimize harming themselves in the anticipated fall. In cases associated with bronchial asthma the treatment of after-cough syncope consists of intensive treatment of the bronchial asthma.

Segmental Gastric Resection for Treatment of Peptic Ulcer.—MacLean and associates present a critical evaluation of segmental gastric resections as performed at the hospital of the University of Minnesota during the last two and one-half years. The results obtained in 90 patients treated with this method were compared with those in 953 patients, who earlier underwent Billroth 2 type gastric resections between the years of 1940 and 1949 for benign lesions of the esophagus, stomach, or duodenum. It was found that segmental gastric resection in which all but 10 to 15% of the acid-secreting area of the stomach is resected is a satisfactory operation for peptic ulcer when accompanied by pyloroplasty. Not only benign gastric and duodenal ulcer, but also esophagitis and lower esophageal stricture were treated successfully with segmental resection. In the presence of supraduodenal ulceration or a scarred and deformed duodenum, the difficulties of closure or anastomosis in this area can be avoided by utilizing segmental resection. Postprandial distress occurs early after segmental resection, but anemia and recurrent ulceration were never observed in the careful follow-up of 90 patients. Food intolerance was limited to milk, ice cream and sweets, but this was frequently encountered. Eighty-eight per cent of the patients lost weight compared to their weight five years before operation. The average weight loss was 19 lb. (8.6 kg.). Over 90% of the patients felt they were improved or greatly improved by the operation. Four patients felt they had not been helped. On the basis of technical advantages, physiological aspects, and careful postoperative evaluation, the authors consider segmental gastric resection a superior operation for the acid peptic diathesis to the *Billroth* 2 procedure.

Radical Gastrectomy for Benign Gastric Ulcer.—The common surgical procedure for gastric ulcer, according to Boyden, is removal of the lower two-thirds of the stomach. For the ulcer proving to be malignant such an operation is entirely inadequate. Were it possible to determine at operation which gastric ulcers are malignant, then wide excision of the lymphatic bed could be performed in those cases. But with the stomach in his hand, the surgeon cannot tell the malignant from the benign ulcer, and it is usually no more apparent to the pathologist on gross examination. Biopsy of the ulcer margin may miss the area of malignancy. Excision of the ulcer for frozen section is commonly misleading because of the difficulty of accurate interpretation by this method in this organ. Excision of the ulcer for immediate examination is often impractical because of its location or adherence to adjacent organs. Biopsy of one or two lymph nodes is inadequate. The ideal treatment of carcinoma of the stomach is total gastrectomy with excision of wide segments of the duodenum and esophagus and removal of all of the greater and lesser omenta, the gastrocolic omentum, and the spleen. Admittedly a compromise, radical subtotal gastrectomy should include all of the zones of lymphatic spread. Boyden reviewed the records of all patients operated on at the Portland Clinic for gastric ulcer and carcinoma during the 6 years from 1946 to 1952. During this interval 70 patients with gastric ulcer were operated on. Pathological examinations were made in 66 cases (eliminating 3 cases of perforated ulcer and 1 of vagotomy and gastroenterostomy). Eight of these lesions were malignant. During the same period (1946 to 1952) 74 patients were operated on in the Portland Clinic for carcinoma of the stomach. These include the 8 with malignant ulcers mentioned previously. Twenty-four lesions were inoperable. Subtotal gastrectomy was undertaken in 38 cases, total gastrectomy in 8, partial esophagogastrectomy in 4. The operative mortality in all resections was 14%. The author advocates subtotal gastrectomy for all gastric ulcers.

Streptokinase-Streptodornase in Thoracic Empyema.—Finnerty reviews the evolution of the treatment of empyema and gives particular attention to the use of streptokinase-streptodornase, which, in addition to making the purulent exudate less viscous, accomplishes several other objectives: It breaks up loculations, converts the empyema space into a single one, and thus renders it more available to the action of locally instilled antibiotics. It also obviates the necessity of needle aspirations in multiple sites. Organisms trapped in the fibrin mesh are liberated and are more liable to the action of antibiotics. The fibrin peel on the pleural surfaces is lysed, thus enabling the lung to expand and obliterate the dead space. This debridement of the pleural surfaces probably also allows the antibiotic, as well as the patient's own leukocytes and antibodies, to enter the infected area and exert their effect. The streptokinase-streptodornase is supplied in moisture-proof sterile ampuls, each ampul containing approximately 100,000 units of streptokinase and about ¼ that amount of streptodornase. About 100,000 to 200,000 units of streptokinase are diluted in 30 to 40 cc. of sterile isotonic sodium chloride solution and are injected into the empyema space. From 8 to 18 hours later thoracentesis is performed. Many patients require only one or two treatments, but some require many. The most important point is that, after injection of the enzymes, complete aspiration must be done, because the enzyme action is self-terminating and, if the lysed material is not removed, redeposition of fibrin will occur. Most failures are due to inadequate removal of liquified material or to the enzymes not having been injected into the proper area in adequate dosages. Because of this and because of the fact that patients frequently object to multiple thoracentesis, it occurred to the author that the use of antibiotics and enzymes in combination with surgical closed intercostal drainage with active suction might represent a further advance in the therapy of empyemas. The obvious advantage of this method over that just described is that constant drainage should shorten the therapy and be more comfortable for the patient and less time consuming for the physician. Accordingly, 15 patients were treated by this method. The conditions included putrid empyemas, lung abscess with large bronchopleural fistulas, and Friedländer's abscess with fistula and empyema. The method obliterated the empyema spaces and rendered more suitable for surgery those in which excision was indicated. The plan of this treatment and several case histories are presented.

Radioactive Cobalt in Postoperative Treatment of Bronchial Carcinoma.—Schneidrzik and associates use a solution of radioactive Cobalt (Co^{60}), which had proved effective in the treatment of bladder tumors. The relative harmlessness of this form of irradiation for the adjoining structures had been proved by experiments on dogs. The authors chose a Foley catheter as the most suitable container for the radioactive solution. The construction of the Foley catheter with its thick and thin tubes and rubber balloon is described. After pulmonary resection the catheter is placed into the thorax in such a manner that the balloon, which can be inflated to a capacity of about 35 cc., rests on the hilus. The catheter is secured by means of a thread above and below the balloon, which, when empty and collapsed, can be pulled out from beneath these securing sutures. Both tubes of the catheter are led outward through an intercostal space. On the ninth postoperative day about 35 cc. of radioactive cobalt solution is placed into the balloon through the small-caliber tube. The patient now has to be isolated so that others will not be damaged by the gamma radiation, readily detectable in the surroundings of the patient with the aid of a Geiger counter. The radioactive fluid is suctioned off from five to seven days later. The histories of three patients in whom this form of irradiation was employed after pneumonectomy are cited. This form of intrathoracic irradiation was comparatively simple, reduced the time required for irradiation, impaired the patient's general condition only slightly, and insured favorable distribution of the ray dosage.

Patent Ductus Arteriosus with Pulmonary Hypertension.—Observations were made on 40 patients, including 24 children of the ages of 3 and 11 years, 14 young adults, not older than 30 years, and 2 adults 54 and 65 years old. The diagnosis of the congenital abnormality was confirmed by passing the catheter into the ductus and into the thoracic aorta in 34 patients, and by operation in six. The patients were placed in three groups with regard to the degree of pulmonary hypertension: group 1 included those between 30 and 60 mm.; group 2, those with 61 and 100 mm.; and group 3, those with 100 and 136 mm. The clinical symptoms, roentgen signs, and the electrocardiogram in the 14 patients of the first group were typical of a patent ductus arteriosus. In the 14 patients in the second group and in 12 in the third the changes observed corresponded to the degree of hypertension. In the patients of the second group, the continuous typical murmur changed into a double systolic and diastolic murmur. Both the left ventricle and the right ventricle were enlarged and showed strain in the electrocardiogram. The shunt was from the aorta into the pulmonary artery. In 11 of the 12 patients in the third group the continuous murmur had disappeared and was replaced by a systolic murmur heard at the base of the heart. A diastolic rumbling murmur, resembling that of mitral stenosis, was heard in three patients. Both ventricles were greatly enlarged, but the enlargement of the right ventricle masked the enlargement of the left. The electrocardiogram showed marked strain of the right ventricle. In severe cases the flow of blood through the patent ductus became crossed and the patients showed a diffuse cyanosis, which was particularly intense in the lower half of the body. The clinical signs were uncertain. The diagnosis was arrived at by sounding the patent ductus. The severe type of pulmonary hypertension is more frequent in children than in adults, suggesting that the condition is primary and not the result of the shunt. Surgery may control hypertension or may prove ineffective. Diagnosis of the syndrome of a patent ductus arteriosus with pulmonary hypertension is possible without catheterization if the patient with a congenital heart disease, with or without cyanosis, presents a systolic murmur at the base of the heart, an electrocardiogram with right ventricular strain, in absence of a polyphasic QRS in the sixth lead, and a radiological picture of pulmonary hypertension with pulsation along the entire left cardiac border of the shadow, which sometimes reaches the hilar vascular shadows.

Familial Hypertrophic Pyloric Stenosis.—In the family cited by Fenwick, hypertrophic pyloric stenosis was discovered at operation in a man, aged 39. He subsequently revealed that two of his four sons had had the Ramstedt operation (pyloromyotomy) performed upon them in infancy, and he had a nephew treated medically for this condition in infancy. In addition, his eldest brother died in infancy from persistent vomiting. The case histories of the man, his two sons, and his nephew (son of his sister) are presented. In this last case the trait passed through a female member of the family. The occurrence of pyloric stenosis in one adult and three children in this family supports the contention that the adult and infantile conditions are the same and that a familial incidence does exist. In the infant, the Ramstedt operation is accepted as the standard procedure. In the adult a variety of procedures have been adopted. They include Ramstedt's sphincterotomy, finger dilatation of the pylorus, plastic procedures on the pylorus, gastroenterostomy, and gastrectomy, either partial or subtotal. The object of surgical treatment is to relieve the obstruction, and this is best done by removing it altogether. The man, whose case is reported, had high normal acidity. A Billroth 1 partial gastrectomy was performed, approximately half the stomach being removed. The result is satisfactory. If the acidity is low, Billroth 1 pylorectomy as recommended by McCann and Dean would seem to be equally satisfactory in that the lesion is removed and a relatively large stomach remnant remains.

Emergency Thoracotomy in Spontaneous Hemothorax.—The purpose of this report is to emphasize the serious nature of spontaneous hemopneumothorax, to stress that its onset may be delayed after the onset of the accompanying spontaneous pneumothorax, and to report two cases with massive spontaneous pneumothorax, both of which were successfully treated by emergency thoracotomy. Evacuation of blood and blood clot from the pleural cavity, control of the bleeding-point, and immediate reexpansion of the totally collapsed lung, was followed by rapid recovery and return to normal life. The third patient, seen three weeks after the onset of the hemopneumothorax, required decortication of his lung. A review of the literature disclosed that 19 of 91 previously reported cases were fatal. Only four patients, including the two reported here, have so far been treated by emergency thoracotomy. Massive spontaneous hemopneumothorax is a surgical emergency which is best treated by resuscitation of the patient, early emergency thoracotomy, evacuation of the blood and blood clot, control of the bleeding-point, treatment of the causative lesion, and the induction of an artificial pleurisy to prevent recurrence. With emergency thoracotomy recovery can be rapid and complete.

A Blood Group Chimera.—Dunsford and collaborators report the case of a blood donor, a woman, aged 25, whose blood when grouped seemed to be a mixture of A and O cells, for anti-A serum caused large agglutinates to appear to the naked eye but the microscope showed these agglutinates to be set in a background of unagglutinated cells. The appearance was such as might be seen for a time after a large transfusion of O blood into an A recipient, but the woman had never received a transfusion. Further samples of her blood ruled out the possibility of accidental mixing of bloods. Observations on this woman's blood called to mind the work of Owen in 1945 on "immunogenetic consequences of vascular anastomoses between bovine twins." Anastomoses are usually present between bovine twin embryos; primordial red cells belonging to one twin take root in the other twin and continue throughout the life of that animal to produce red cells with genetically foreign antigens. Chorionic vascular anastomosis and transfer of endocrine secretions between bovine twins of different sex had been postulated as the cause of the freemartin condition by Lillie as early as 1916. When asked if she were a twin, the woman donor, somewhat surprised, answered that her twin brother had died 25 years ago at the age of 3 months. This woman is the first human being to be shown to have a double set of blood groups, and there can be little doubt that this is the consequence of vascular communication with her twin. Though hematologists have been prepared for this discovery by the work of Owen on bovine twins, such a mixture of blood cannot be common in human twins: the Blood Group Research Unit tested the blood of 58 pairs of dissimilar twins and 82 pairs of apparently identical twins without finding evidence of mixed blood groups.

Oxytetracycline (Terramycin) in Relapsing Fever.—The tick-borne type of relapsing fever, which is prevalent in Israel, is known to be resistant to arsenicals, penicillin, gold, and bismuth compounds. Gefel and Rubenow point out that experiments carried out by Adler and co-workers proved that oxytetracycline has a specific influence on rats inoculated with Spirochaeta persica. The authors themselves used oxytetracycline in the treatment of seven cases of relapsing fever. The drug was given orally to two, intravenously to four, and intramuscularly to one. A relapse occurred in one patient treated orally with 55.5 mg. per kilogram of body weight daily for five days. In all patients receiving parenteral treatment, the temperature dropped within 24 hours, clinical signs disappeared gradually, and the blood was cleared of parasites within a few hours, in one case within 45 minutes. The importance of the blood sedimentation rate in the prognosis of relapsing fever is emphasized. Relapses occurred in four cases of nonspecific treatment in which the sedimentation rate did not return to normal levels after the fall of the temperature. Acquired hemolytic anemia, due to the action of the spirochetes, developed in two of the patients; this complication has not been reported before.

Cancer of the Breast in Israeli Women.—A statistical study of cancer of the breast in Israeli women revealed that it occurs with a frequency about twice that given in the literature for other countries. During the years 1945-1947, 1,760 malignant tumors were found and 394 cases (22.3%) were of cancer of the breast. Only 9% of the women were of Oriental origin, while the proportion of these women in the whole population was 26% in the period under survey. Eleven per cent of the women were unmarried or married but sterile. The author believes that the increase of breast cancer is a result of late marriage and limited fertility. Where birth control is being practiced, it has been accompanied by an increase of mammary cancer. Figures of success rate in cancers of stage 1 and 2 are compared with results reported in the American literature. The somewhat higher success rates in Israel are attributed to the fact that Israeli women consult their physicians early.

Folic Acid Excretion Test in Intestinal Malabsorption.—Girdwood points out that the term "sprue syndrome" has been used recently to include the features found in idiopathic steatorrhea of nontropical origin and in celiac disease. Since the introduction of the fat balance test of Cooke in 1946 it has been extended to include cases with megaloblastic anemia and deficient absorption of fat, but little other clinical evidence of intestinal malabsorption, and the term "malabsorption syndrome" has come into use. The seeming paradox of treating a condition believed to be due to malabsorption of hemopoietic factors by giving these same substances orally has led to the hypothesis that the fault in nontropical sprue is malabsorption of naturally occurring folic acid conjugates rather than of folic acid itself. The present investigation indicates that there is, in fact, considerable deficiency of absorption of folic acid in sprue, and that advantage can be taken of this to devise a test of folic acid absorption and excretion for the diagnosis of malabsorption by the small intestine. The author describes a comparison of urinary excretion of folic acid following subcutaneous and oral test doses of 5 mg. of folic acid in 11 cases of intestinal malabsorption, 15 cases of pernicious anemia, 14 controls, and 5 patients with pregnancy anemia. This test revealed impairment of absorption of folic acid only in patients with the malabsorption syndrome or with iron-deficiency anemia refractory to therapy with iron by mouth. Megaloblastic anemia of pregnancy subsequently responding to folic acid therapy may occur without biochemical evidence of a failure in absorption or tissue depletion of folic acid. Since it may be necessary in intestinal malabsorption to load the tissues with injected folic acid before performing the differential folic acid excretion test, time may be saved by doing this in all instances before the test is carried out. From the laboratory point of view a fat balance test is easier to perform, but it requires hospitalization of the patient so that a suitable diet can be given and its consumption supervised, and furthermore the stools must be collected for several days. The differential folic acid excretion test may be of particular value where steatorrhea is not obvious and there is refractory megaloblastic anemia, refractory iron-deficiency anemia, or unexplained glossitis. If further work confirms the value of the folic acid excretion tests, the diagnosis of sprue should, at least in some instances, be rendered easier in that special diet is not required and specimens of urine can be sent for assay from other hospitals to laboratories in which folic acid tests are being done. It is not yet possible to say whether a positive fat-balance test may be associated with a negative folic acid excretion test in the "malabsorption syndrome."

Hyperpotassemic Paralysis.—According to Bull and associates, much has been written in recent years about the dangers of a high concentration of potassium in the plasma, especially in the anurias, in Addison's disease, and following the administration of potassium. The greatest danger of hyperpotassemia is, of course, that of sudden death from cessation of heart action in diastole. Other features of hyperpotassemia are lassitude and clouding of consciousness, although these do not always occur. Finally, flaccid paralysis occurs rarely. The authors cite three patients with hyperpotassemic paralysis. In the first of these patients the paralysis recurred several times in the terminal stages of a subacute glomerulonephritis. In the second patient this symptom was present during an Addisonian crisis, from which he was rescued by appropriate therapy. The third patient, with renal failure due to renal tuberculosis, presented the symptom in the last days of illness. The mechanism of hyperpotassemic paralysis remains obscure, but it is suggested that it is an acute peripheral neuropathy.

New Estrogen in Treatment of Carcinoma of Prostate.—When estrogen is used in the treatment of prostatic cancer, not only do the pressing clinical symptoms disappear and the metastases retrogress but microscopic examination of sections of the prostate after treatment may reveal no evidence of carcinomatous cells but rather a washed-out structure of large enucleated cells. It is now regarded that at least a contributory factor, if not the real cause of the relapse, in prostatic carcinoma being treated by estrogens, is hyperactivity of the hormonal phase of adrenal function. It has been proved experimentally that the continuous administration of the usual estrogens to laboratory animals causes enlargement of the pituitary and the adrenal glands. In the search for estrogens that did not have this stimulating effect on the adrenal and pituitary, studies were made with the estrogen chlorotrianisene (TACE). Although this drug produces characteristic estrogenic effects, it differs from diethylstilbestrol and hexestrol in that it does not have the same pronounced effect on the pituitary and the adrenals. The author cites animal experiments with this drug and describes his own clinical experiences with it. He has used the drug for only a short time and in a small number of cases. At first it was given in cases in which no further improvement could be achieved with estrogens commonly used. In other cases, the change to the new estrogen was made because of the painful and embarrassing manifestations of gynecomastia. The large, painful breasts and tender nipples in persons who take diethylstilbestrol over a long period of time often compel the reduction of the dosage, or the patient himself will cease taking the drug. The use of the new estrogen has invariably resulted in an amelioration of these distressing symptoms, and when used immediately after diagnosis, no evidence of feminization has been found or it has been very slight. The property of fat storage exhibited by the new estrogen seems to explain why it has a more prolonged effect. Because the drug is liberated slowly, the patient with prostatic cancer may develop a more constant level of estrogenic stimulation, which is more effective than the varying amounts of stimulation that follow the treatment with the estrogens in common use up to now.

Needle Biopsy of Liver.—The authors performed 108 needle biopsies of the liver with the technique of Iversen and Roholm in 77 patients. The biopsy diagnosis was confirmed by autopsy in all but one of the patients who died. This patient was a heavy drinker in whom diagnosis of pernicious anemia with indications of fatty cirrhosis of liver had been made. Autopsy revealed instead alcoholic steatosis with an occasional mesenchymal reaction of the portal-biliary spaces. The results of liver function tests coincided with the histological picture of the biopsy specimens in many patients, especially in those with nonfatty cirrhosis and neoplasms. Biopsy was the decisive diagnostic factor in patients with fatty cirrhosis and pure steatosis. Needle biopsy of the liver is indicated in all liver diseases of undetermined cause, in differential diagnosis between parenchymal and extrahepatic obstructive jaundice, and in primary or metastatic neoplasm of the liver. It is valuable in determining the type of cirrhosis present and in evaluating the course of chronic hepatitis and the effects of therapy in liver disease. Histological examination of serial biopsy specimens may reveal improvement in some instances in which laboratory tests do not reveal an improvement. Needle biopsy of the liver may also help in the diagnosis of some systemic disease. In fact, the changes that occur in the liver during infectious mononucleosis, diabetes, pellagra, and amyloidosis have already been studied by other authors. It is contraindicated in patients with a low prothrombin level. The authors never performed it in patients whose prothrombin concentration, as determined by Quick's method, was not above 40% of the normal. It is also contraindicated in patients with septic cholangitis, hepatic echinococcosis, bacterial or amebic abscesses, and ascites. Uncooperative patients and children are also, as a rule, excluded. The severest complication of needle biopsy of the liver is fatal hemorrhage. This is rare, and occurs mainly in patients in whom the prothrombin concentration was not considered. The authors had no complications in their patients.

Habitual Abortion Caused by Wide Uterine Isthmus.—Swaab presents the case of a woman, aged 37, whose three previous pregnancies had resulted either in abortion or premature labor, despite treatment with vitamin E, progesterone and stilbestrol. Examination disclosed an abnormally wide internal uterine os and a lengthening of the isthmus, which had resulted from a previous curettage. In such cases the external uterine os is not necessarily ruptured and the uterine cervix when examined through a speculum may appear to be intact. The author shows the roentgenologic shadow of such a uterus side by side with that of a normal one, and he also shows a diagram of a cross section of such a uterus. The condition can be recognized when a uterine dressing forceps passes the internal uterine os (isthmus uteri) without difficulty. Rupture of the membranes prior to the onset of labor is characteristic of this condition. In the reported case the condition was corrected by surgical treatment, in which the cervix, particularly at the level of the isthmus, was narrowed with the aid of catgut sutures. Favorable results obtained by others with this intervention indicate a favorable prognosis.

Fetal Asphyxia and Its Treatment.—Fetal asphyxia occurred in 833 (2.25%) of 37,000 deliveries in the gynecologic department of the Södersjukhus from 1943 to 1951; 545 of the mothers were primiparas. In almost half the cases the fetal asphyxia was caused by prolonged labor; in one-third of the cases it was due to abnormally intensive uterine contractions. The commonest symptoms were changes in the rhythm and frequency of the fetal sounds and discharge of meconium. Ninety-eight cases (11.8%) were fatal. Treatment consists in the first place in prophylactic measures to promote delivery before fetal asphyxia occurs. Intense pains threatening to cause fetal asphyxia can be subdued by narcosis and confluent pains be limited by injections of morphine. Fetal mortality is decreased by more active management of labor. Interventions necessary to save the life of the fetus play an important part in the prognosis. If an intervention is not possible, heart activity may be stimulated by injections of heart stimulants to the mother. Asphyxia after birth is treated according to the nature of the case. In 553 cases removal of mucus from the respiratory passages gave good results. Cyanosis in 144 cases in which the infant was blue was treated by various measures, including agents stimulating heart and respiratory activity, with favorable results, and in 38 of the 79 cases in which the baby was white treatment with artificial respiration, heat, and oxygen was successful.

Long-Acting Corticotropin in Bronchial Asthma in Children.—Bergstrand and his associates administered corticotropin (ACTH) with prolonged action to 11 children, aged from 5 to 13, with grave asthma of long standing resistant to the usual antiallergic treatment. Thirteen asthmatic children, aged from 4 to 14, were treated with the regular corticotropin preparation. If a rapid corticotropin effect is desired in asthmatic attacks endangering life, regular corticotropin is preferred. To break a long-continued status asthmaticus, treatment with either the regular or the long-acting corticotropin can be applied with about the same favorable temporary effect, improvement as a rule setting in more slowly with long-acting corticotropin. With this preparation, however, ambulant treatment is possible, which means a limited number of injections, at intervals of days, and a comparatively small dose, reckoned by the day, and allows treatment for longer periods without too great danger of side-effects.

*Gamma Globulin, a Blood Derivative, in Therapy. V. Lamarca.—p. 847.
Subcutaneous Calcification with Rare Course: One Case. L. Cancellotti. —p. 853.

Gamma Globulin in Therapy.—One of the latest discoveries in the field of immunology is the identification of antibodies with gamma globulin of human serum. This achievement explains the increased emphasis on and interest in this important blood derivative. Gamma globulin was first used as a prophylactic against measles in 1938. It prevented the onset of the disease if it was inoculated within five days from the date of exposure and gave only partial immunity if it was given later. It proved especially valuable in children in poor general condition with tuberculosis and acute respiratory disease who had been exposed to the infection. Passive immunization lasted for two to three weeks, with the patient's age, degree and duration of exposure, virulence of the virus, and individual condition of immunization playing a great part on the outcome of the therapy. Since gamma globulin contains not only specific antibodies against measles but also a wide range of other antibodies, it was later used for passive immunization against other infections. It gave good results in whooping cough, epidemic parotitis (by preventing onset of orchitis), epidemic or infectious hepatitis, and post-transfusion hepatitis. It was used later in sepsis of infants and roseola infantum. The greatest usefulness of gamma globulin, however, is as a prophylactic against poliomyelitis. This is based on the concept that most human beings overcome the infection without the paralytic symptoms that are characteristic of the disease. This occurs because the virus enters the organism but does not reach the nervous tissue. The infection thus does not become manifest, but specific antibodies are formed. Preliminary reports from the United States, where research studies and experiments are being carried out on a large scale, indicate that passive immunization against poliomyelitis was secured with gamma globulin for at least five weeks. These results are encouraging, but a longer period of observation and further studies are needed for a final evaluation.

*Prolonged Sleep Treatment in Medicopsychiatric Practice by So-Called Hibernation Method. A. Deschamps and M. Cadoret.—p. 878.

Prolonged Sleep (Hibernation Method) in Psychiatric Medical Treatment.—Prolonged sleep as used by the authors differs from artificial hibernation because it is induced principally by drugs, and refrigeration is used merely as a supplementary measure. The depth of the sleep and the duration of the treatment are less important than the degree of relaxation secured.

Treatment by this method proved safe even in aged, hypertensive, and cardiac patients. Strict medical supervision is required, and the ganglion-blocking agents used to obtain neurovegetative inhibition should be withdrawn gradually at the close of the treatment. The sleep produced is calm, and the patients are relaxed and indifferent. Breathing is regular, the pulse is usually normal, and there is almost always a drop in the blood pressure. Prolonged sleep was used in treating 15 patients with various psychiatric conditions who had not been benefited by other methods of treatment or whose general condition was too poor for shock therapy. The best results were secured in patients who had symptoms of agitation and confusion and severe melancholic anxiety, but substantial improvement was also noted in patients with mania.

Late Results of Surgical Treatment of Epilepsy.—Of 110 patients between the ages of 4 and 49 years who had focal cortical epilepsy demonstrated by an abnormal electrical activity originating from a limited point or zone of the cerebral cortex and who had been operated on and followed up postoperatively for from six months to four years, 82 had obtained good or excellent results. Of the 82 patients, 27 no longer had convulsions despite complete discontinuation of drugs, and they did not have any sequelae; 27 patients had no sequelae and no longer had convulsions but still required administration of a reduced dose, 0.10 gm., of phenobarbital sodium; 9 patients no longer had convulsions but persistent neurological sequelae that were compatible with a good social readaptation; the remaining 19 patients had one or two attacks of convulsions in the course of one year. Twenty-three patients were improved having less attacks of convulsions despite the administration of a reduced dose of drugs as compared to the time before the surgical intervention. Five patients were therapeutic failures; one died, one became worse, and three were unchanged. The author emphasizes that the patient operated on had had persistent attacks of convulsions despite prolonged treatment with antiepileptic drugs. The selection of patients for surgical intervention was based essentially on electroencephalographic criteria. Surgical intervention was carried out under corticographic control following excision step by step until any abnormal electrical activity had disappeared. Partial or complete therapeutic failures were essentially due to the impossibility of proceeding with the resection of the epileptogenous cortical area without running the risk of producing some motor weakness, sensorial diminution, or a disturbance of speech when a significant zone of cortical representation had been invaded by the eliptogenous area. Considering the benign character of the surgical intervention and the favorable results obtained in patients with severe cortical epilepsy, it seems justified to extend surgical treatment to less serious cases provided that the electroencephalographic criteria prove particularly favorable. By extending the indications for surgical intervention it may be possible to detect and to apply treatment to a tumor with a slow course whose only clinical manifestation consists of a convulsive state.

Surgical Treatment of Tumors of Bladder. M. Sorrentino.—p. 597.
Procaine Amide in Therapy of Supraventricular Paroxysmal Tachycardia. A. Tommaselli.—p. 601.
*Insufficient Use of Active Therapy in Chronic Pulmonary Tuberculosis. G. Censi and P. Maraschio.—p. 607.

Inadequate Treatment of Chronic Pulmonary Tuberculosis.—Although the mortality rate for pulmonary tuberculosis in Italy has decreased, the average period of treatment and hospitalization for patients with the disease has increased. Therapy with antibiotics did bring about rapid and frequent recoveries, but sooner or later there were relapses with more and larger cavities that prolonged the course of the disease. Incompetence of the phthisiologist in selecting the best treatment, inadequate psychological preparation of the patient, inadequate surgical equipment, and economic factors are responsible for this discouraging situation. Chronic cavities can be eliminated definitively with proper and timely surgery. Divergencies that arise on the selection of the best surgical procedure are easily eliminated if treatment is individualized and the method that guarantees the best results with the least risk is applied. Pulmonary resection and collapse therapy are the treatment of choice in chronic pulmonary tuberculosis. The former is especially indicated in patients whose lung tissue is destroyed, those with stenosis of the main or the lobar bronchus, and those with tuberculoma. The collapse therapy should be employed in patients in whom the resection is contraindicated. It gives better results than intrapleural or extrapleural pneumothorax. A review of the literature revealed that, of 100 patients in whom pulmonary resection was performed after streptomycin became available, only 7 had died within three years, whereas, of 100 patients who were treated medically in sanatoriums before the antibiotic era, only 24 were still living five years later. Of 100 patients in whom pneumothorax was induced before streptomycin became available, 45 died within five years, whereas, of 100 in whom lobectomy or pneumonectomy was performed, only 13 had died two to four years later. Approximately 90% of the patients with chronic pulmonary tuberculosis can be cured with pulmonary resection, if it is performed before any other surgical treatment and before resistance to antibiotic therapy has developed.

Type and Form of BCG Skin Lesion. F. Puntigam and K. Berger. —p. 559.
*Hormonal Regulation of Dentition. L. J. Baume.—p. 560.

Endangiitis Obliterans of Kidney and Hypertension.—Fellmann and Zollinger report two patients with endangiitis obliterans and involvement of the kidneys. In one of these the blood pressure remained normal while the necropsy revealed very extensive, but rather recent renal infarcts. The second patient died with signs of malignant hypertension. In this patient, autopsy disclosed multiple fresh renal infarcts interspersed with ischemic areas of the parenchyma. The latter were apparently result of subtotal arterial obliteration by endangiitic lesions. The authors point out that for decades after endangiitis obliterans had been described by von Winiwarter and Buerger, it was considered chiefly a disease of the arteries of the extremities. During the last two decades more and more observers have called attention to the involvement of vessels of parenchymatous organs. The existence of "coronary" Buerger's disease has been established beyond a doubt, and cerebral involvement has likewise been established. Reports about endangiitis obliterans of the kidney have been so far rare.

Hormonal Regulation of Dentition.—Baume chose the incisors of rats to study the hormonal regulation of dentition. These have the advantage that the eruption is continuous and is not limited to a certain period as is the case in human beings. The following three experiments were made: 1. Thyroidectomy was done on the day of birth, and subsequently the animals were treated with growth hormone and thyroxin. 2. Hypophysectomy was done on the 28th day and the animals were observed for various periods of time. 3. Growth hormone and thyroxin were administered following hypophysectomy. It was found that hypophysectomy had a more decided effect on dentition than did thyroidectomy. The hypophysis influences dentition not only by its thyrotropic, but also by its growth hormone. Thyroid hormone and hypophyseal growth hormone have fundamentally differing effects on dentition. Thyroid hormone influences the size as well as the eruption of the tooth and is the most important hormonal factor in dentition. It has a specific effect on histological differentiation of the epithelium and is capable of inducing the formation of bone tissue in the growth cartilages; for this reason it has been designated as the maturation hormone. Its general stimulating effect on the metabolism produces increased vascularization in the dental tissue. While the growth hormone has a much more decisive effect on the size of the tooth than does thyroxin, it is not able to promote tooth eruption following hypophysectomy. As an activator of the protein metabolism thyroxin has a stimulating effect on all mesenchymal tissues and has a special affinity for the cartilaginous growth disks. In the described experiments this became manifest in the activation of pulpa growth, in dentinogenesis and in the membranous bone growth of the alveolar process. The mechanism of tooth eruption cannot be completely dissociated from growth, in that proliferation of the odontogenic tissue is the basic process, and in this the growth hormone is most important. To insure that the tooth not only increases in size but also erupts, the dental and peridental tissues require a different tempo of growth. The organ which determines this differentiation is definitely the odontogenic epithelium, which is regulated by the thyroid hormone. Deficiency of this hormone causes disturbances in the proliferation of the odontogenic epithelium, and this in turn causes primary malposition of the tooth papillae and later inhibition of eruption. Retarded eruption of the tooth germ with continued root growth suggests mild hypothyroidism, provided that rickets, vitamin A deficiency and sternocleidocranial dysostosis can be ruled out. Treatment with thyroid extract will stimulate the eruption of these retained teeth, provided treatment is tolerated long enough. Generally retarded eruption with greatly retarded germ development is suggestive of cretinism, and requires on the basis of experimental observation combined administration of thyroid extract and growth hormone.

Electrical Data in Mitral Heart Disease: Clinical, Anatomical, and Operative Comparisons (115 Cases). E. Donzelot, R. Heim de Balsac, G. Dauzier and others.—p. 1968.

Efficacy of Massive Doses of Vitamin B_{12}.—Small doses of vitamin B_{12} may benefit convalescent patients and others whose need for the vitamin is not absolute, but when it is imperatively required, it should be given in massive doses. A single intramuscular injection of 1,000 mcg. of crystalline vitamin B_{12} has been found adequate to maintain a normal blood and marrow picture for from 128 to 358 days in 15 patients with pernicious anemia, indicating that the vitamin can be stored in the body. Similarly large doses have also proved effective in various neurological and rheumatological conditions, such as multiple sclerosis, polyneuritis, and trigeminal neuralgia. Vitamin B_{12} is well tolerated and, like other members of the vitamin B complex, entirely nontoxic, whether given orally or parenterally. Marked improvement and in some cases an apparent cure of progressive pernicious anemia has been secured by the daily administration of 1,000 mcg. When given intramuscularly, injections of 1,000 mcg. every other day are enough to produce satisfactory results in ordinary cases without severe nervous complications. The use of vitamin B_{12} in massive doses is economically advantageous because it shortens the period of hospitalization and frequently results in cure of the patient.

*Late Results of Commissurotomy and Its Indications. P. Soulié, F. Joly, J. Carlotti and J. Baillet.—p. 2105.

Immediate Postoperative Results of Commissurotomy.—The immediate postoperative results of commissurotomy fall into three groups: (1) the inevitable disturbances and discomforts of the first few days after the operation; (2) complications of varying severity; and (3) deaths. The postoperative course in favorable cases is comparatively uneventful. Fever, which is constantly noted, is of short duration; the pain caused by the operative wound usually diminishes rapidly; pleural effusions require from two to five tappings; and the pericardial reaction is latent and can only be detected in roentgenograms. Patients may be allowed up in about a fortnight and can leave the hospital three or four weeks after the operation. Many continue to have parietal pain in the scapular region for some time and find it difficult to move the left shoulder. Disturbances of cardiac rhythm, thromboembolic accidents, and acute postoperative pulmonary edema are the principal complications observed during the first four to six weeks after surgery. The first two can often be corrected by appropriate treatment, but the third indicates that the operation aggravated an existing mitral regurgitation. No matter how great the skill and the experience of the surgeon, there are cases in which the valves are so profoundly altered and ineffective that intervention will inevitably increase the systolic reflux. Postoperative deaths may be due to embolism, cerebral thrombosis, or the existence of irremediable changes in the mitral valve. A syndrome of cyanosis during surgery and postoperative collapse causing death within 48 hours has also been observed. This syndrome apparently occurs when mitral stenosis is accompanied by high pulmonary hypertension with an elevated arteriocapillary pressure gradient and extensive pulmonary lesions. Autopsy showed the lungs of patients in whom this was observed to be hypervascularized, brownish, firm, and resistant. All efforts at therapy were ineffectual, and the appearance of cyanosis at the beginning of anesthesia should be taken as an indication for abandonment of the operation.

Late Results of Commissurotomy and Its Indications.—Four classes of patients with mitral stenosis may be subjected to commissurotomy. Class 1 includes patients with little functional disturbance in whom cardiac catheterization shows elevated pressures and in whom electrocardiography indicates that the right side of the heart is being subjected to strain. Commissurotomy in these patients is a preventive measure and the mortality accompanying it should be negligible. Patients in class 2 have severe dyspnea or suffer repeated attacks of pulmonary edema. The hemodynamic disturbances revealed by catheterization of these patients are severe, and their functional incapacity is complete. Commissurotomy gives excellent results in three-fourths of these cases, and the operative mortality does not exceed 4%. The operative indications in class 3 patients are the most difficult to determine. Functional disturbance is severe, and mitral stenosis has usually resulted in the first stages of cardiac insufficiency. The operative risk in these patients is great and results in a mortality rate of from 15 to 20%; excellent results, however, are sometimes obtained. Class 4 patients are those with total arrhythmia, severe heart failure of several months' or years' duration, and greatly enlarged hearts; their condition is sometimes improved by the operation, but the operative mortality is very high. Commissurotomy should not be a routine procedure in mitral stenosis; the benefit to be expected from it and the risks accompanying it should be carefully evaluated with due regard for the fact that in spite of their disability many patients with mitral stenosis reach the age of about 60 with medical treatment alone.

Prognostic Significance of Small Tumor in Cancer of Breast.—In Kreyberg and Christiansen's 974 cases of cancer of the breast examined from 1933 to 1942, which allowed at least 10 years' observation of the later fate of the patients, there were only 56 carcinomas (5.7% of the entire number) of the size of a hazel nut or smaller, and only 10 were as small as a pea or a bean. The authors conclude that over half of the patients with cancer of the breast having a tumor of the size of a hazel nut or smaller will succumb to the disease after receiving the treatment applied today. This is true even for the smallest tumors in the series; of the 10 patients with such tumors 5 are living after 10 years and 4 have died from metastases. The minimal cancers of the breast do not as a group definitely give a better prognosis than does an ordinary average group of cancers of stage 1 and stage 2 that receive the same treatment.

Application of Serum and Vaccine Against Tetanus. H. Andersen.—p. 906.

Poliomyelitis Epidemic in Copenhagen in 1950.—From late June, 1950, to the end of the year 110 cases of paralytic and 636 cases of nonparalytic poliomyelitis were treated in Blegdam Hospital. Children predominated, and there was a slight preponderance of males in the nonparalytic cases. The frequency of paralysis, in 15% of the entire group, the degree of severity, and the mortality increased with increasing age. Pregnancy seemed to increase morbidity and frequency of paralysis. There were also 136 cases of probable poliomyelitis, and 19 cases of polyradiculitis are considered because of their occurrence during the epidemic period. The epidemic curve reached its peak in September. The epidemic curve for polyradiculitis corresponded to that for poliomyelitis, but the age average was higher than that in poliomyelitis.

Cardiac Affections in Poliomyelitis.—In the opinion of Georg and his associates a specific myocarditis may perhaps occur in some cases of poliomyelitis, but the majority of the histological and electrocardiographic changes described in this disease can undoubtedly be explained as results of anoxia and disturbances in the pulmonary circulation in patients with respiratory difficulty.

Spontaneous Pneumothorax. L. Neuner.—p. 455.
*Pheochromocytoma and Hypertension. H. Hartl.—p. 467.

Plasmacytoma of the Lung.—The occurrence of an extramedullary plasmacytoma of the lung, a relatively rare tumor, is reported in a 16-year-old girl. For about one year the patient had transitory painful swellings of the fingers, occasional pains in the arms and legs, occasional night sweats, and lancinating pains in the area of the right shoulder on respiration. A round shadow the size of an apple was demonstrated on roentgenologic examination in the area between the middle and lower lobe of the right lung. The blood count revealed normal number of erythrocytes and leukocytes; changes of the albuminoid bodies could not be demonstrated. Roentgenologic examination of the skeleton revealed stratified periosteal bony cuffs on the phalanges of the fingers and on the metacarpal bones of the hands, as well as on the ulna and on the radius. An endobronchial plasmacytoma of the lower lobe of the right lung was removed by lobectomy. The postoperative follow-up was much too short for the morphological disappearance of the new growth of bone, but the patient no longer complained of pain. The hyperplastic osteopathy is a valuable symptom in the diagnosis of pulmonary tumors. Microscopic differentiation between metastasizing and benign tumors is not possible. New foci may occur by metastasis despite the distinct demarcation of the plasmacytoma. Radical treatment by surgical removal of the tumor is advocated.

Pheochromocytoma and Hypertension.—According to Hartl, the incidence of pheochromocytoma is higher than it is generally assumed. Hypertension may be caused by a pheochromocytoma in about 0.5% of all patients with hypertension. Paroxysmal episodes of hypertension are not the only characteristic of pheochromocytoma, since in most patients the tumor may cause a persistent, labile hypertensive state. Pheochromocytoma should be thought of in the differential diagnosis of a patient with hypertension. Diagnosis of pheochromocytoma may be aided by the modern chemical tests with such substances as histamine, metacholine chloride, epinephrine, or tetraethylammonium chloride. These tests are not specific for pheochromocytoma and not free of risk. Tests with adrenolytics, such as Dibenamine (N,N-dibenzyl-β-chloroethylamine) hydrochloride may be of even greater aid in the diagnosis, but in the author's experience pneumoradiography of the retroperitoneal space after parasacral injection of air is the method of choice in demonstrating the tumor, because both adrenals may be visualized in one stage and the risk of air embolism is less than with the injection of air into the perinephric area. Surgical removal of the pheochromocytoma is not difficult, but the labile blood pressure makes the anesthesiologist's task difficult. Administration of Dibenamine preoperatively and in the course of the intervention may prevent a catastrophe due to liberation of epinephrine caused by manipulation of the tumor. Arterenol provides protection against reactive hypotension. Despite the microscopically benign findings, pheochromocytoma should be designated as "functionally malignant," since death may result within a short time if surgical removal is not carried out. Seven illustrative cases are described in five men between the ages of 20 and 42 and in two 30-year-old women. In one of these the tentative diagnosis of pheochromocytoma could not be confirmed on necropsy. Three patients, one of them with a mixed type of pheochromocytoma and adrenal cortex tumor, made a complete recovery after surgical removal of the tumor.

Stress Effect of Blood Transfusion.—Möller and Wendland discuss the fate of some of the constituents of transfused blood, particularly of the protein, and the effects of the transfusion on the bone marrow, blood picture and circulation. They believe that blood transfusion produces a stress reaction. Determining the eosinophil counts of 10 patients, they found that in 8 the transfusion was followed by a noticeable decrease in eosinophils. They investigated the excretion of 17-ketosteroids in the urine in seven patients and found a noticeable increase following transfusion in five of these. Either a decrease in eosinophils or an increase in the elimination of corticoids was observed in 15 of 17 patients after blood transfusion. Possibly some of the effects of blood transfusion represent reactions typical of Selye's adaptation syndrome; these include changes in the blood and plasma volumes, disturbances in the permeability of the cell membranes and of the capillaries, increase in diuresis, changes in the blood pressure, in the proteins, in the blood picture and in the bone marrow. According to Selye, the picture of the adaptation syndrome rarely appears in the pure form, but it is partly obscured by the specific effect of whatever agent is active. This masking by the specific effect of blood transfusion makes evaluation difficult.

Primary Double Carcinomas. H. Wiesner.—p. 426.

Erythrocytopathia Punctata Granuliformis in an Adult.—Brugsch and Tichter describe a new entity to which they apply the term "erythrocytopathia punctata granuliformis." The disorder was observed in a woman, aged 42, but the authors feel that it is related to an anemia of the newborn, in which the erythrocytes are characterized by the presence of inclusion bodies, and which was described by Gasser and Willi. In the woman, whose history is presented, the erythrocytes of the peripheral blood disclosed spontaneous formation of Howell-Jolly bodies, appearance of normoblasts, target cells, macrocytes, and reduction in osmotic resistance. Although there was no aplasia of the spleen, as Gasser and Willi had observed in their cases, splenic dysfunction could be suspected in the presence of hepatic cirrhosis with severe changes in the blood proteins. Malformations of the blood vessels (multiple hemangiomas) and defective toes were present. These and other defects in a woman, who was born of consanguineous parents, suggest severe generalized cellular abnormalities, and it is suggested that a generalized disturbance existed in the synthesis of proteins or of ribonucleic acid. The granula of the lymphocytes also showed abnormalities. The authors feel that in their patient the hepatic disorder, hypothrombinemia, and changes in the blood proteins with gamma-hyperglobulinemia were of importance in the pathogenesis. Splenic disturbances in cases of this type presumably are not the essential cause, but only an important eliciting factor. The high nucleosidase content of the spleen might be related to the decomposition of erythroblastic nuclei in the bone marrow. Formation of defective erythroblasts with pathological protein and nucleoside formation would then promote the formation of Howell-Jolly-like bodies in the presence of dysfunction or even agenesia of the spleen.

Behavior of Mineral Level in Blood Serum After Injection of Tetraethylammonium Bromide. H. Kleinsorge and K. Linde.—p. 499.

Side-Effects of Isoniazid Preparations.—Isoniazid was given first in doses of 10 to 15 mg. and later in doses of 5 to 6 mg. per kilogram of body weight, daily in four divided doses, to 147 adult patients with pulmonary tuberculosis of all types, including those with exudative pleurisy. Fatigue and somnolence were noted most frequently during the first days of treatment. In 6 patients these phenomena continued for three weeks. The incidence of these side-effects was higher with the dose of 10 mg. per kilogram of body weight than with the smaller doses. Fatigue and sleepiness in an 18-year-old girl were associated with refractory constipation and disturbances of micturition during the first five days of treatment. Sensations of burning, furred feeling, formication, smothering, and lancinating pains in hands and feet were observed in 16 patients. These paresthesias occurred after four weeks of treatment (14.5 gm. of the drug) at the earliest and after six months of treatment (73.9 gm.) at the latest. They occurred in 11 patients after three months of treatment. The paresthesias subsided very slowly. Administration of nicotinic acid amide, and a proprietary crystalline vitamin B_1 (Betabion) proved ineffective except in one patient. Twenty-one patients complained of dizziness, 5 of headache, and 11 of a sensation of pressure in the frontal region of the head. Seven patients had transient palpitation, and in one patient with arteriosclerosis complaints of an angina pectoris type required discontinuation of the drug. Eczema, rash, and pruritus occurred in six patients. Five patients complained of nausea and occasional vomiting during the first weeks of treatment; in one patient these side-effects recurred after three and a half months of treatment and required discontinuation of the drug. In only seven patients a serious condition developed consisting of mental confusion, meningism, circulatory disturbances, and polyneuritis. The author believes that there is a relationship between incidence and severity of the side-effects and the dosage of the drug and partly also of the type of the tuberculous disease. The side-effects probably depend on the length of time the drug is administered. Arteriosclerotic changes and previous damage due to drugs or disease may favor the occurrence of untoward reactions. A specific therapy does not seem to be effective. In two of the author's patients manifestations of polyneuritis did not subside for many months after discontinuation of the drug. The side-effects of isoniazid are not entirely harmless. Despite that, treatment in a hospital or sanatorium may be continued in ambulant patients provided that the patient's condition will allow it and definite control of the patient is guaranteed.

Problems of Immunity in Malaria. E. G. Nauck.—p. 285.
*Arthropods as Hosts of Causal Agent of Q Fever (Rickettsia burneti). F. Weyer.—p. 344.
*Rabies: Morbidity and Mortality in Exposed Persons. L. Gremliza. —p. 382.

Causal Agent of Q Fever (Rickettsia burneti): Arthropods as Hosts.—Weyer describes experiments on bloodsucking arthropods to ascertain whether or not they were potential hosts of Rickettsia burneti and thus may become vectors of Q-fever. Ticks (Ornithodorus moubata), body lice, fleas, bedbugs, and larvae of meal worms were infected with rickettsial material by sucking or by intrarectal and intraperitoneal application. Whereas, under natural conditions, Rickettsia burneti is found only in various species of ticks, all of the above named arthropods proved more or less susceptible when experimentally infected. Rickettsias multiplied rapidly in the coeloma and intestinal cells without serious damage to the host; they also spread occasionally to other organs and were excreted with their virulence unchanged. Contrary to other rickettsias, Rickettsia burneti seems highly adaptable to various organs and cell types of heterogeneous arthropods, most of which, however, do not act as natural hosts, carriers, or transmitters. Considering the favorable conditions for the survival of Rickettsia burneti, one wonders why Q-fever is not more prevalent.

Rabies: Morbidity and Mortality in Exposed Persons.—Of 32 persons attacked by a rabid wolf in a rural district in Persia, 19 were bitten about the head, 3 on face and neck, and 10 on hand or arm. Four of the six who received antirabic treatment remained free from symptoms and two died. In the two treated patients who died symptoms of the disease were evident before treatment was begun. Of the 26 patients who received no antirabic treatment, 13 died and the other 13 remained free from symptoms and survived. The mortality rate was over 50% among the patients who had been bitten on face, scalp, or neck; in those who received bites on arm or hand the mortality was lower. The incubation period averaged 24 and 27 days after head and neck bites, respectively, and 45 days after arm and hand bites. It is pointed out that even severe lacerations caused by rabid animals do not necessarily lead to death when left untreated. Similar conclusions were reached by another investigator who reported on human rabies resulting from the bites of rabid wolves in February, 1952.

BOOK REVIEWS

Practice of Psychiatry. By William S. Sadler, M.D., F.A.P.A., Consulting Psychiatrist to Columbus Hospital and Pinel Sanitarium, Chicago. Cloth. $15. Pp. 1183. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

Dr. Sadler is one of the grand old men of American psychiatry, having begun his contributions to the literature more than 40 years ago. He has done much to popularize psychiatry, not only among the laity but among nonpsychiatric practitioners as well. In this contribution, he has attempted to give us a "book to serve as a ready and compact reference for diagnosis and immediate treatment." What he has given us actually is a great collection of data from his active professional life of many years. The result is an almost overwhelming collection of facts, theories, and personal opinions combined in an interesting style that belongs to another age of medical writing. One can hear Sir William Osler in the following quotation: "After two or three visits with the patient, I concluded there must be something on her mind, and, discerning to disposition on her part to disclose it, made bold to probe more deeply; finally, when she was asked whether she was worrying over autoeroticism or over some slip of propriety in her relations with her lover, she indignantly denied the latter and tacitly admitted to the former."

The final result is unique. The book is not a reference book, a textbook, or a manual, despite its attempts to be all these things; it is a compendium of psychological and psychiatric knowledge since the time of Adam. In this sense it is a historical survey of interest to psychiatrists and workers in this field but certainly neither a textbook for students of medicine nor a manual for practitioners. Dr. Sadler's book includes such interesting chapter headings as: "Psychiatry and Psychiatrists," "Mental and Emotional Mechanisms," "The Health and Happiness Pathoses," "What Is Personality?" "The Sexual System," "Therapeutic Study Program," "Philosophy and Religion," and "Will-Power and Decision." There are 75 chapters, a 40 page appendix, "Schools of Psychiatry," and an extensive glossary.

That such a work, covering almost 1,200 closely printed pages, must contain much that is questionable and must often consist of a synthesis of the thoughts of others is inevitable, because no one can have accurate and sensible ideas about every aspect of psychiatry. This does not criticize Dr. Sadler's abilities or honesty but only emphasizes the impossibility of the task he set for himself. In general, he can be criticized for neglecting reasonable explanations, or the causes of emotional illness, and substituting for them lengthy descriptions of psychopathology that may increase the student's knowledge but certainly do not help his understanding of psychiatric disease. In his discussion of involutional melancholia, Dr. Sadler does well in not relating the depressive aspects to hormonal changes directly, but he fails to give the reader a clear concept of why the patient becomes depressed at this period of his life. The author takes a wise and broad-minded view of sexual problems but again often stops at the descriptive level without giving a clear explanation of the causes. Interestingly the list of sexual perversions includes dyspareunia along with necrophilia, sodomy, and fellatio. This type of poor arrangement of data is seen repeatedly throughout the book. The chapter on personality is extensive and compiles many of the current theories; however, long quotations from Bluemel, with attempts at explaining the lives of Napoleon, Joan of Arc, Hitler, etc., are out of place in this book.

It would be difficult for the practitioner to arrive at any type of useful therapy from the author's descriptions; however, these are most interesting. A quotation from the chapter "Therapeutic Study Program" states: "Mathematics is an excellent memory developer, and when the neurotic sees his memory improving, he is tremendously encouraged and throws himself enthusiastically into new efforts to gain the mastery of his nerves." A daily reading program that the author outlined for one of his patients reads: "Tuesday, 9:30 a. m.—The second chapter in the Gospel of St. John; 2:00 p. m.—Nature Study, first three chapters of book on Ants; 7:30 p. m.—memory exercises, Problems in Mental Arithmetic (under direction of patient's husband)." The author also catalogues little-known methods of treatment that can be found only in this book; for example, "cold mitten friction technique" and the use of electric "auto-condensation," are explained. A "deep massage of the abdomen," using "a small cannon-ball over the abdomen with the patient lying down," is described. Certainly Dr. Sadler brings us many worth-while bits of personal philosophy and a broad and humanistic approach to disturbed interpersonal relationships. On the other hand, these things have not combined to produce a generally useful medical text. Dr. Sadler is to be commended for his courage in attempting to put together the best contributions of an extensive and difficult field into a usable collection for medical men. He has failed to produce this, but he has produced a volume of general historical interest to all specialized workers in the field of psychiatry. Nowhere else can such a tremendous collection of unsifted material be found in one place.

Manual práctico de medicina interna (compendio de patología y clínica médicas). Por Alexander von Domarus. Redactado de nuevo y puesto al día por Hans Frh. von Kress, docente y médico-jefe del Departamento de medicina interna del Hospital Lazarus, de Berlin, Pedro Farreras Valenti, profesor a. de patologia y clínica médicas en la Facultad de medicina de Barcelona, y Egidio S. Mazzei, profesor titular de clínica médica en la Facultad de medicina de La Plata. [Título de la edición original alemana: Grundriss der inneren Medizin.] Fourth edition. Cloth. Pp. 968, with 84 illustrations. Manuel Marín y Cía., editores, Provenza 273, Barcelona, 1953.

The object in writing this volume was to introduce and serve as a guide to medical students and young physicians in the vast field of internal medicine. In it, therefore, the author has expressed his ideas in clear, simple elementary terms, using only the indispensable theoretical terms necessary to clear understanding. In this revised and enlarged edition, as in the previous one, numerous errors have been corrected and discussions carried on in more detail. The goal of the writer was to simplify it as much as possible to make it easy for students as well as the busy practitioner to assimilate. The chapter on infectious diseases has a much more modern approach than heretofore and includes treatment with new drugs and antibiotics. New chapters have been added. The printing is in a larger and bolder type, making reading easier.

An Atlas of Surgical Exposures of the Extremities. By Sam W. Banks, M.D., Associate Professor of Orthopedic Surgery, Northwestern University Medical School, Chicago, and Harold Laufman, M.D., Ph.D., Associate Professor of Surgery, Northwestern University Medical School. Cloth. $15. Pp. 391, with 552 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

This book is essentially a reference book in which the exposures of the long bones and of the pelvis and shoulder girdle, etc., are collected. The illustrations are clear, and practically all emphasize the points that the authors wish to make. Type and format of the book are good. The style of writing is attractive and clear. The names of the surgeons who first described the various exposures have not been mentioned. It seems a pity that the great names of the past have been passed over. It also would be an advantage to include a brief discussion of the merits and demerits of each exposure. At present, the book is merely a collection of exposures that have been described and not critically analyzed. It will, however, make for itself a place in surgical literature, and it deserves to be on the book shelves of all orthopedic surgeons.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specificially so stated.

Fathers Are Parents, Too: A Constructive Guide to Successful Fatherhood. By O. Spurgeon English, M.D., and Constance J. Foster. Cloth. $3.75. Pp. 304: G. P. Putnam's Sons, 210 Madison Ave., New York 16, 1951.

The relation of parents to their children is a very delicate one, but under the pressures of modern living the tendency for the father to be too busy to share with the mother the family responsibilities of child rearing has raised a question of whether or not he is necessary. The authors not only emphasize that he is very necessary but in great detail instruct him how to increase his value to his children, when to be forthright and positive in this relationship, and when to hold back and watch development.

This book appears to be intended for the intelligent lay reader. Because it is based on analytical psychiatry and is filled with the technical terminology of this discipline, it demands the most careful kind of reading. It is not recommended for casual reading, because it is certain to be misunderstood. The book will, therefore, appeal to a very limited number of readers informed in the field of psychology and psychiatry. Much of what is said about the reasons for certain behavior on the part of fathers and mothers and children, and particularly the behavior in regard to the relations among these persons, is so presented that a parent who has not followed the prescribed narrow path will be filled with guilt feelings and possibly will require the services of the psychiatrist who, in this book, is attempting to help him. This book should be of interest to physicians and counselors who are well enough informed on analytical psychiatry and the principles on which the book is based to understand the implications that it states. It would be confusing and possibly dangerous for the uninitiated reader.

Conduction Anesthesia. By George P. Pitkin, M.D., F.A.C.S., F.I.C.A. Edited by James L. Southworth, M.D., F.A.C.S., Robert A. Hingson, M.D., F.A.C.A., F.I.C.A., and Winifred M. Pitkin, B.M., B.Ch., M.D. Second edition. Cloth. $22.50. Pp. 1005, with 585 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

In the first edition of this work, which appeared in 1946, some of the chapters were written by seven additional collaborators. This second edition represents the pooling of knowledge and experience of a surgeon, an anesthesiologist, and a clinician and anatomist. Extensive revisions of some chapters have been made. Other chapters have been rearranged or expanded to include changing concepts. New chapters have been added dealing with the vertebral canal and its contents, including "landmark" anatomy; topical anesthesia for the ophthalmologist and the oral and general surgeon; and a valuable discussion of complications of conduction anesthesia, including cause, prevention, and treatment. The material on pharmacology has been brought up-to-date. More extensive discussion of extradural anesthesia by single and continuous methods of administration appears in this revised edition. The chapters originally written by Dr. George P. Pitkin remain almost unaltered and still form the foundation of this volume.

At the end of the 20 chapters is an extensive bibliography, followed by a bibliographic index, and an adequate general index. Unfortunately the bibliographic index contains numerous errors due mainly to repetition of several authors' names caused by failure to include some initials, as well as mistakes made in initials or in the spelling of names.

This attractively bound book is on paper of excellent quality, the type is clear, and the illustrations are well selected. The general format is excellent. While it is too detailed for medical students, except as a reference book, it is highly recommended to surgeons, anesthesiologists, and practicing physicians.

Chemistry of Carbon Compounds: A Modern Comprehensive Treatise. Volume II, Part A: Alicyclic Compounds. Edited by E. H. Rodd, A.C. G.I., D.I.C., D.Sc. Contributors: R. G. R. Bacon, Ph.D., A.R.C.S., et al. Cloth. $12.50; to subscr. $11.25. Pp. 487. Elsevier Press, Inc., 402 Lovett Blvd., Houston 6; 155 E. 82nd St., New York 28; 118 Spuistraat, Amsterdam C, Netherlands, 1953.

The third book in a series succeeding Richter's "Organic Chemistry" is virtually a monograph by R. A. Raphael, of Glasgow, on the chemistry of alicyclic hydrocarbons and their derivatives. The first chapter covers the theory of the structure and stability of saturated ring compounds containing only carbon in the ring. In the next eight chapters Raphael takes up the chemistry of the different sorts of alicyclic compounds. The compounds range from those containing single rings of all sizes to the more complex spiro, fused ring, and bridged ring compounds. The material forms a foundation for the chemistry of the terpenes and steroids, which will be covered in part B of volume 2.

The only material in part A not written by Raphael is a short chapter on carotenoids by Hunter and a somewhat longer chapter, by Bacon, on open-chain and cyclic polymers, such as natural and synthetic rubber and rubber-like compounds. As in the other parts of this series, each topic is treated briefly, and the reader is referred to original and review articles and to monographs for further information. The material is arranged logically and is well indexed. The paper and printing are excellent, and the binding is sturdy.

Classics in Clinical Dermatology with Biographical Sketches. By Walter B. Shelley, M. D., Ph.D., Chief, Clinic of Dermatology, University of Pennsylvania Hospital, Philadelphia, and John T. Crissey, M.D., *Instructor*, Dermatology and Syphilology, University of Pennsylvania. Introduction by John H. Stokes, M.D., Professor of Dermatology and Syphilology, Graduate School of Medicine, University of Pennsylvania. Cloth. $10.50. Pp. 467, with 108 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

In this most entertaining and literate work Shelley and Crissey have collected the significant and classic dermatological descriptions from the early physicians of the 18th and 19th centuries to those of modern times. This book is the first of its kind in the field of dermatology. The 143 descriptions, all in English, include both common and rare diseases, entities as old as psoriasis and others as modern as tropical anidrosis. Each of the classics is preceded by a brief interesting biographical sketch of its author, 95 men "who differed in every conceivable way, race, age, time, background, education, temperament, and ability, but who had one faculty in common, the ability to perceive the new as new." The book is, in a sense, a historical survey presented not as a succession of names and dates but with a young and lively perspective free from adulation but properly respectful of the masters. The authors have carefully edited the papers so as to limit the accounts to clinical descriptions, omitting all laboratory particulars. Many of the original illustrations and photographs of most all of the original writers are reproduced. The publishers have cooperated to produce a magnificently turned-out book. It should be in the library of every student of medicine.

Histology. By Arthur Worth Ham, M.B., F.R.S.C., Professor of Anatomy, in Charge of Histology, in Faculties of Medicine and Dentistry, University of Toronto, Toronto. Second edition. Cloth. $10. Pp. 866, with 518 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

This edition of Ham's "Histology" is published three years after the original publication and contains new material and revisions of chapters concerned with the cell structure, the connective tissues, bone, the impulse conducting system of the heart, the lymphatics, the liver, the lungs, and the adrenal cortex. Part 1, in four chapters, defines histology and how it is studied. Part 2, in six chapters, discusses the cells, the intercellular substances, the tissue fluids, the blood cells, platelets, and fibrin. Part 3, in 10 chapters, describes the four primary tissues, epithelial, connective, muscular, and nervous, and their subdivisions. And part 4, in 10 chapters, details the histology of the systems, such as circulatory, integumentary, digestive, respiratory, urinary, endocrine, female reproductive, male reproductive, sensory receptive, and articulative. The text is complete in descriptive details, is well and generously illustrated, the illustrations are of uniformly good quality, and the references are sufficient. This book is highly recommended for students and teachers of histology and to pathologists as an excellent reference.

QUERIES AND MINOR NOTES

TREATMENT OF HODGKIN'S DISEASE

To the Editor:—*A 31-year-old naval officer's wife has Hodgkin's disease. I have been treating her with corticotropin (ACTH) and testosterone, and lately have thought of using cortisone in conjunction with the above treatment. Would this be advisable? The disease is quite active as shown by lymphadenopathy in the cervical and skull areas.*

M.D., Pennsylvania.

Answer.—The treatment of Hodgkin's disease remains essentially a treatment by roentgen therapy. This should be given in small doses, i. e., 300 to 600 r over the affected lymph nodes. Some recommend that it be given over groups of lymph nodes adjacent to the affected area even though these are not enlarged. Great attention should be paid to maintaining a normal red blood cell count and avoiding leukopenia. Blood transfusions should be employed without hesitation when indicated, and absorbable forms of iron should be frequently administered. Testosterone does not affect the disease process and can only contribute to the patient's sense of well-being. Cortisone does not affect the disease process but might be employed in the presence of anemia or hemolytic anemia if either develops. Cortisone will also contribute to stimulation of the normal elements of the bone marrow should this be necessary. In addition to roentgen irradiation, the most valuable agent in Hodgkin's disease is nitrogen mustard. This drug is employed either alternating with series of x-ray treatments or when x-ray irradiation seems to have lost its effect. Under the latter situations, nitrogen mustard will bring about a remission of acute phases of the disease. Sole reliance cannot be made on nitrogen mustard, nor does x-ray therapy represent the sole treatment without the use of nitrogen mustard as an adjuvant when necessary. The maintenance of adequate caloric intake and general nutritional status is of utmost importance. Newer drugs such as 6-mercaptopurine have not been found as efficacious in Hodgkin's disease as in certain leukemias. The problem of when to use x-rays and when to use nitrogen mustard and how long to continue use of these agents rests on clinical judgment and no set rule can be given. The patient's condition is the true guide to treatment. Over-treatment must be avoided, as the efficacy of both x-rays and nitrogen mustard decreases progressively as time goes on, and, therefore, these agents must be husbanded as much as possible for as long as possible in order to have some agents available that will be effective in bringing about a remission when acute phases of the disease develop.

MALIGNANT HYPERTENSION

To the Editor:—*A man, 30 years of age, has malignant essential hypertension. His blood pressure averages 250/160 mm. Hg, he has 4+ albumin in the urine, he is losing weight rapidly, and his vision is failing. An electrocardiogram shows considerable heart damage, although the patient has not clinically had a heart attack, nor has he had heart failure. A sympathectomy is not indicated. Trial with all the usual hypotensive drugs has produced no improvement. Tests for a renal or adrenal tumor gave negative results. Recently, a patient of mine was told that some kind of injections are being used in the treatment of hypertension, with dramatic results. Please advise what drug this is.*

Donald F. De Morse, M.D., Holbrook, Ariz.

Answer.—The medicament oftenest used parenterally to reduce blood pressure of patients with hypertension is hexamethonium bromide, which is available under the trade name Bistrium. Another drug recommended for intravenous use is Veriloid (hypotensive ester alkaloids of veratrum viride). Other preparations for similar use are available. General experience indicates, however, that patients with severe malignant hypertension respond poorly. Most authorities believe that the hazard of use of strong hypotensive drugs in such patients is too great. Reduction of blood pressure may be associated with increased renal failure and uremia, cardiac or cerebral ischemia, and perhaps thrombosis. Conventional medical dietary treatment with use of commonly employed drugs for sedation and symptomatic relief would be best for the patient described. Even adrenalectomy has not yielded encouraging results in this type of severe malignant hypertension.

THROMBOCYTOPENIC PURPURA

To the Editor:—*In a 39-year-old woman petechiae of the extremities developed during the fifth month of pregnancy, followed by mild, transitory epistaxis, coffee-colored stools, and ecchymosis of the ankle. The blood cell counts are within the normal range, but the initial platelet count was 20,000 per cubic millimeter. The only drugs the patient has been receiving are diethylstilbestrol in increasing amounts, at present about 50 mg. daily, and Boyle hematinic tablets (ferrous gluconate with vitamins B complex and C), six daily. The patient's past history includes a normal pregnancy, a miscarriage at four months followed by severe bleeding for one month, another normal pregnancy, and an early abortion. About 18 months ago she had hematuria and pyuria, which were treated with triple sulfonamides; an episode of petechiae that followed was thought to be due to drug sensitivity, and no platelet count was done at that time. The condition cleared spontaneously. The patient had one other episode of petechiae, without alarming sequelae. She is a redhead. For the present episode, treatment has consisted of administration of cortisone, 100 mg. daily, and testosterone, 100 mg. daily intramuscularly, for one week. At the end of four days of treatment, the platelet count was 26,000 and at the end of one week, 21,350. The diethylstilbestrol therapy was stopped abruptly. What is the best method for further managemet of this case? Is there any justification for using diethylstilbestrol? Is there any danger in withdrawing diethylstilbestrol abruptly?*

Michael Irvin, M.D., Tacoma, Wash.

Answer.—This patient obviously has thrombocytopenic purpura, which is a syndrome of many different causes. It may be idiopathic (Werlhof's disease), or it may be caused by a variety of infectious granulomatous, neoplastic, allergic, or toxic conditions. This patient may be sensitive to diethylstilbestrol, although this is not likely. If diethylstilbestrol were responsible for the thrombocytopenia, the platelet count would return to normal after use of the drug was stopped. A bone marrow biopsy should be done to determine whether any changes have taken place in the megakaryocytes (an increase in number, decreased granularity and absent platelet production, and an increase in the number of immature forms, promegakaryocytes and megakaryoblasts). There seems to be little justification for the use of diethylstilbestrol, and there is no danger in withdrawing it. Redheads have no particular bleeding difficulties in pregnancy; this is simply a superstition. If the patient has idiopathic thrombocytopenic purpura, cortisone administration may have to be continued; although it may not raise the platelet count, it will decrease the capillary permeability and the tendency to bleed. If the bleeding tendency persists, splenectomy is indicated and can be performed by a skilled surgeon without causing abortion in the fifth month of pregnancy. It would be advantageous to determine whether the patient has evidence of the presence of antiplatelet autoagglutinins (see Harrington, W. J., and others: *Ann. Int. Med.* 38:433, 1953).

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. *Anonymous communications and queries on postal cards cannot be answered.* Every letter must contain the writer's name and address, but these will be omitted on request.

TREATMENT FOR TRICHOMONAS VAGINITIS

To the Editor:—*Please comment on an office procedure by which apparently I was able to cure a case of Trichomonas vaginitis. An applicator well soaked in hydrogen peroxide was inserted into the cervix and left in place for at least one minute. This was repeated four or five times at each treatment or until the cervical canal appeared "clean." Silver nitrate, 8%, was next applied once or twice at each treatment. Treatments were given at 7 to 10 day intervals. After about six treatments the patient was free of symptoms. The smear was negative, and the patient has remained symptom-free for two years.* *M.D., New York.*

Answer.—The method proposed is not approved for the following reasons: 1. Silver nitrate does not eradicate granulations or inflamed tissue and may, in the strength suggested, cause cervical stricture. 2. The use of a foaming agent, such as hydrogen peroxide, in the cervical canal is apt to cause bacteria from the cervix to be pushed up into the uterus and thus may lead to pelvic inflammatory disease. 3. Often repeated cervical treatments lead to chronicity of infection and lowered resistance of the tissue. The source of Trichomonas vaginitis still is not known, but most gynecologists agree that the proper treatment consists of the following measures: (1) the cleaning up of local irritations, such as erosions: this is usually done by direct cautery; "cherry red" hot cautery is used, with stellate linear incisions starting in the endocervix and carried out to the mucocutaneous junction; care must be used to leave tissue between the cautery strokes untouched so that the epithelium may regenerate; this treatment should not be repeated within six months to a year and, therefore, the first treatment should be thorough enough to promote drainage and destroy most of the granulating tissue of the erosion; (2) the use of an agent that will on contact kill the trichomonads and that will not damage tissue; (3) the use of an acid agent that will increase the pH of the vagina toward normal to promote growth of Döderlein's bacilli (Bacillus vaginalis), the natural bacteria of the vagina, and will discourage the growth of other bacteria; (4) use of an agent, such as one of the sugars, that will also aid in promoting growth of Döderlein's bacilli. Several suppositories are available that fulfill the needs of the last two measures.

The treatment will be successful only if simple and if persisted in. The patient should begin by taking a vaginal suppository twice daily for one week, with no douches. During the second and third weeks the suppository is used only at night. Douching is not recommended at all unless the patient on occasion notices that accumulated material from the suppositories bothers her; in such an event she may douche, using low pressure and weak lactic acid or vinegar and allowing the fluid free egress from the vagina. If a douche is taken a suppository should be inserted soon after so that the vagina is constantly covered by the suppository material. After the third week the frequency of use of the suppositories is decreased to every other night for two weeks, then every third night, then two times weekly, and finally once weekly. During the treatment it is important if any bleeding or a menstrual period occurs that the patient again take suppositories twice a day until the bleeding stops, after which treatment is resumed at the point reached when bleeding occurred. With this method, few failures occur. The patient should treat herself for three to six months. Intercourse is allowed, unless the husband harbors the organism in the prostate.

The situation should be explained to the patient in advance of treatment. The persistence necessary and the fact that treatment should not be stopped as soon as symptoms disappear should be stressed. It is surprising how few visits are necessary to the physician's office if this routine is carried out. A few variations in treatment occasionally are necessary. In a fair percentage of patients with this infestation the cervix and vagina are so tender that examination is almost impossible. This makes insertion of a suppository painful at first. In these cases, an extremely weak vinegar or lactic acid douche is used two or three times over 24 hours before the regular treatment is started. Cauterization is done as soon as the acute inflammation subsides, usually on the second visit or at the end of one week, if it seems necessary.

TYPHUS

To the Editor:—*What is the effect of antibiotic treatment on the rising antibody titer in typhus? Will the titer continue to rise and enable the physician to verify the diagnosis even after subsidence of the acute fever, which usually occurs promptly after institution of chloramphenicol therapy, or will the titer remain stationary at the level reached when antibiotic therapy was instituted?*

Heinrich Lamm, M.D., La Feria, Texas.

Answer.—Treatment of patients with typhus with the broad spectrum antibiotics generally has little effect on the development of antibodies. Patients given chloramphenicol, chlortetracycline (aureomycin), or oxytetracycline (Terramycin) late in the first week or early in the second week after the onset may be expected to show a rising titer of Weil-Felix agglutinin, increasing from a low or negligible level on the eighth day to a maximal level during the third week. Patients given specific therapy during the first few days of fever, actually before the clinical diagnosis can be made, often show a delay in the appearance of the Weil-Felix agglutinins. Such persons may have low or negligible titers at the end of the second week, but antibodies appear in a good titer by the end of the third week. Before specific therapy became available for the typhus and spotted fever groups of the rickettsial diseases, patients remained febrile for two weeks and convalesced for a month. Late serum samples were easily obtained under these conditions. With the present therapeutic measures, patients have shortened periods of disease and convalescence and may be out of the hospital before maximal antibody levels are reached. In such instances, it may be desirable to have the patient return 4 to 5 weeks after the onset of the disease for a check-up and to supply a late sample of serum for the serologic diagnosis.

INHERITANCE OF ICHTHYOSIS SIMPLEX

To the Editor:—*A 28-year-old man has congenital, generalized ichthyosis simplex of moderate severity. There is no known familial history or stigmata of the trait. If he were to marry a woman with normal skin, what would be the chances that his offspring would inherit ichthyosis?*

William Snyder, M.D., Paterson, N. J.

Answer.—Two types of inheritance for ichthyosis simplex have been described, simple dominant and sex-linked recessive (Gates, R. R.: Human Genetics, New York, The Macmillan Company, 1946, vol. 1, pp. 313-315). The former is commoner and is frequently seen in persons of northern European stock, whereas the latter is said to occur mainly in Latin and Japanese persons. If the person under consideration has the simple, dominant type of ichthyosis simplex, at least 50% of his offspring would be expected to show the condition. If the inheritance is sex-linked recessive and the woman is not a carrier, none of the first generation offspring would show the trait, but all daughters would become carriers, so that 50% of their sons would be expected to show the condition; however, other complicating factors, such as inhibiting genes, may alter these expected percentages.

BACTERIA IN OPERATING ROOMS

To the Editor:—*What is the approximate normal bacteria count in an ideally regulated operating room?*

S. L. Governale, M.D., Chicago.

Answer.—Bacteria settle out of the air in a clean operating room at the rate of 30,000 viable organisms per aseptic field per hour. With careless housekeeping or a dirty air conditioning system the count will rise to hundreds of millions per hour. The following two references are of interest:

Meleney, F. L.: Infection in Clean Operative Wounds: 9 Year Study, Surg., Gynec. & Obst. **60**: 264 (Feb. [no. 2A]) 1935.

NEOPLASMS OF THE SKIN

To THE EDITOR:—*What are the recent developments in the technique of inguinal lymphatic dissection in neoplasms of the skin below the umbilicus? I would like to know the advantages and disadvantages associated with the different procedures currently in use.*

Enoir Nasri, M.D., Damascus, Syria.

ANSWER.—The currently accepted treatment for neoplasms of the skin, exclusive of malignant melanoma, is wide local excision. Subsequent node metastases are managed by radical node dissection, as a secondary procedure. In cases of malignant melanoma, the accepted method of treatment at present appears to be wide local excision of the primary lesion, including all subcutaneous tissue and underlying fascia in continuity, with complete dissection of the lymph nodes of the area most likely to be involved by lymphatic metastasis. The abdominal wall lesion below the umbilicus tends to metastasize to the inguinal and iliac nodes of the homolateral side. Superficial groin dissection may occasionally be done, but most surgeons today favor complete lymphatic dissection in the groin, including superficial femoral, inguinal, iliac and obturator nodes, whenever groin dissection is indicated. This requires splitting the inguinal ligament for retroperitoneal dissection. A review of abdominal wall neoplasms by Pack and Ehrlich appeared in *International Abstracts of Surgery* in 1944. The techniques are described in the references given below.

Pack, G. T., and Rekers, P.: Management of Malignant Tumors in Groin: Report of 122 Groin Dissections, Am. J. Surg. **56**: 545-565 (June) 1942.

AMPLIFYING STETHOSCOPES

To THE EDITOR:—*A physician who has had a hearing loss of about 60% is disturbed at not being able to use a stethoscope. Can you advise where he can obtain an amplifying stethoscope or anything that would be of help?*

M.D., Indiana.

ANSWER.—The development of hearing loss in a physician as it affects satisfactory use of the stethoscope is a serious problem to which no completely satisfactory solution is readily available. Electronic amplifying stethoscopes are available, and some have been accepted by the Council on Physical Medicine and Rehabilitation of the American Medical Association. When a physician attempts to use one of these instruments, he must actually learn to "hear" again. He must become accustomed to the heart sounds as electronically amplified and must again learn to interpret the various sounds he hears, much as he learned the meaning of these various sounds as heard through the conventional stethoscope in his medical school days.

ULTRAVIOLET LIGHT

To THE EDITOR:—*Does the prolonged use of ultraviolet light on the face for acne have any deleterious effects? A 16-year-old girl has been using ultraviolet therapy for acne, and the condition is clearing up, but abscessed teeth are now developing. Is there any connection, or is this a coincidence?*

M.D., Massachusetts.

ANSWER.—Assuming that ultraviolet light was used in the proper exposure, it would, in the earlier stages of its application, produce erythema of the skin, and, subsequently, might cause tanning. There is controversy as to whether excessive ultraviolet radiation itself produces cancer. It is generally felt, however, that ultraviolet radiation may produce precancerous lesions and that trauma (chemical, mechanical, or actinic) to these precancerous lesions may result in malignancy. It is extremely doubtful that there is any connection between the application of ultraviolet light to the patient treated in this case and the development of abscessed teeth.

USE OF THYROID IN ADAMS-STOKES SYNDROME

To THE EDITOR:—*Please explain the therapeutic action of thyroid in the Adams-Stokes syndrome.*

John A. Mangieri, M.D., Gangall, N. Y.

ANSWER.—The therapeutic use of thyroid preparation in the Adams-Stokes syndrome is based on the metabolic action of the hormone on the myocardium. With its use, atrioventricular conduction might be expected to improve, with prevention or reduction in incidence of attacks, and the resulting increased ventricular excitability might be expected to reduce the duration of ventricular asystole and elevate inherent ventricular rhythm. While it has been shown repeatedly that thyroid elevates the metabolic rate and inherent rhythm of both auricle and ventricle in vitro, its effects on the conducting mechanism are less clear, and results of its use in the living patient are more complex. The well-recognized dangers of elevating the metabolic rate in a patient with cardiac damage of the degree usually associated with the Adams-Stokes syndrome would seem to greatly outweigh the possible theoretical benefits to be gained with thyroid therapy.

OVALOCYTOSIS

To THE EDITOR:—*I would like to comment on the query on "Ovalocytosis" in* THE JOURNAL, *July 4, 1953, page 985. It is true that the great majority of carriers of the ovalocytic (elliptocytic) trait are asymptomatic. In many a coexistent anemia has been ascribed to hemorrhage and nutrition. In reviewing these cases it is apparent that a large number manifest findings of overt hemolysis with reticulocytosis, bilirubinemia, and shortened cell survival. In almost every case a dominant hereditary trait was demonstrated. In one case in the literature (Wyandt and others:* Arch. Int. Med. **68**:*1043 [Dec.] 1941) and in one studied in our pediatric ward, both parents carried the trait and the children had marked hemolysis. It may be that a person who is homozygous manifests a marked anemia and the heterozygous patient only the trait. A number of cases have been described in which splenectomy has resulted in marked improvement or virtual cure, as was true of our patient. Some of these have shown a concomitant increased osmotic fragility with or without spherocytes (J. V. Dacie and others:* Quart. J. Med. **22**:*79, 1953).*

It seems advisable, then, to test this child for evidence of a hemolytic mechanism. The parents should also be studied. Of course, a spontaneous rise during iron therapy would preclude such a diagnosis and suggest that she suffers only from the trait and that the anemia is the result of hemorrhage and/or iron deficiency. In any case, bilirubin, reticulocyte, and probably bone marrow studies are indicated.

Earle L. Lipton, M.D.
University of Illinois
College of Medicine
1819 W. Polk St.
Chicago 12.

NERVOUS INDIGESTION

To THE EDITOR:—*The reply of the consultant to the query regarding nervous indigestion in* THE JOURNAL, *July 11, 1953, page 1083, would have been more helpful if the inquirer had been advised to probe more deeply into the life situation of his patient and to elicit the cause of the symptoms. Chapters 11, 12, and 13 of "Psychosomatic Medicine" by Weiss and English (Philadelphia, W. B. Saunders Company, 1950) present this problem well. Any benefit obtained from the Pavatrine (β-diethylaminoethyl fluorene-9-carboxylate) hydrochloride and phenobarbital would probably be due to the sedative effect of the phenobarbital alone. Treatment of the anal impotency with long-continued use of phenolphthalien-containing liquid petrolatum preparations will cause a distressing skin rash in many patients.*

THERAPEUTIC ASPECTS OF GERIATRIC MEDICINE

William B. Kountz, M.D., St. Louis

Perhaps a discussion of geriatric medicine should begin with consideration of the purpose of this field of medical science. Present hospital reports tell the story of persons past midlife. The ever-increasing numbers of persons who are in ill health and are infirm emphasize the need for evaluation of the health in the latter phase of life. In simple terms geriatric medicine and age should have as their prime purpose the same relationship as youth and pediatric medicine, which none can deny is a very important relationship for children. It should be emphasized that medicine has been responsible for the maintenance of life and health well beyond the 45 year average life expectancy at the turn of the century to 65 or 70 years today. Thus, the span of life of a great number of persons has been extended into a period when degenerative disease plays an important role. Medicine has, therefore, a responsibility in keeping the elderly person healthy, particularly since it is responsible for extending his life.[1]

In pediatrics, medicine has learned that there are certain biological weaknesses of childhood such as lack of immunity to common infections like measles, mumps, scarlet fever, and diphtheria. It has learned that if physicians artificially extend immunization they increase health. It has also learned that there are certain feeding problems in children and that low intake of essential food substances brings about disease. For instance, a low intake of vitamin D will cause rickets and lack of adequate protein will bring about inanition.

Studies in the field of geriatric medicine have established that, just as with the child, the older person has certain biological weaknesses that lead to disease.[2] He does not necessarily lack the antibodies and/or readily succumb to infection that is common in childhood, but the strain of life has brought about other functional disturbances that lead to tissue exhaustion and disease. The most probable cause of disease has been found to be exhaustion of body tissue function.[3] This exhaustion is a natural phenomenon, since it can be readily demonstrated that weakness of any body tissue may develop with prolonged overuse without sufficient rest and adequate nutrition of the cells.[4] Geriatric medicine, therefore, must seek its place in the maintenance of health of the older population and prevent or modify the degenerative or exhaustive processes that result in such conditions as arteriosclerosis, heart disease, and mental changes. Just as many of the infections of childhood can be prevented, health in older persons must be preserved and degenerative body changes prevented or modified.

The attitude in medicine has formerly been and still is at present to wait until specific disease entities develop before anything is done about them. A patient may have coronary thrombosis after definite assurance on the part of a physician that his heart is normal. Physicians are more prone to look at the anatomic states of the body than to realize that disturbed body function may lead to and is always a prodromal condition for anatomic diseases associated with degenerative body changes. In order to avoid anatomic disease in these persons, it is necessary that early manifestations of disturbed body function be recognized. Thus, a person may have an attack of coronary heart disease that may be repeated from time to time until he becomes a miserable, marginal worker whose usefulness to himself and mankind has been reduced manyfold. In fact, many such persons become wards of their families, friends, or the communities in which they live. It is needless to say that medicine does not know all the answers in the control of degenerative disease at this time, but the period of 15 years that has elapsed since the research unit in gerontology was established in the St. Louis Infirmary and Infirmary Hospital has seen considerable advancement in the understanding of these conditions.

HEALTH CONTROL

The field of health control for older persons is not well recognized by clinical medicine. Geriatric medicine should emphasize the control of health, and to do this it must not wait until the elderly persons arrive at an

advanced state of ill health.[5] In order for persons to go to the physician at an early period, that is, at 40 to 50 years of age, they, as well as the physician, must be educated. The physician must be educated to recognize functional as well as anatomical changes of the body, and the patient to realize that disease or body change is lurking in the background even though he feels in good health. The very important problem of prevention of degenerative disease, anticipation of health, or health maintenance of the relatively well older person is a field that should be uppermost in present thoughts.

In a study of health one of the important factors is to understand the basic functions of the body as they operate. Such an understanding calls for proper medical evaluation. There are two general causes of chronic illness in the person past midlife. One develops as a result of factors from outside the body organism and causes disturbance and decline that is, and must be, considered of exogenous origin. The other develops as a primary body change and is considered to be of endogenous origin. Examples of the first condition would be scars from old infections, tuberculosis, and mitral valve disease. Occupational diseases would fall into this category. Arteriosclerosis, diabetes, and some forms of arthritis seem to fall into the latter, or endogenous, caterory.

The endogenous processes are believed to arise from chemopathological disturbances in the body and are the more important and far commoner of the two. It is believed that the change results in a decline in the function of tissues, particularly those that have to do with nutrition. Habits and heredity and food perhaps influence the exhaustive factor more than any other state. Therefore, in assessing or studying the control of disease processes in persons past midlife, different factors and combinations must be considered.

The change from a rural to an urban society in our present civilization contributes to a certain type of exhaustive phenomenon of the body related to diseases of the older person today. The tension and stress of living play a role in tissue exhaustion, particularly that of the glands of internal secretion.[6] Factors that thus cause endogenous degenerative changes may be associated with inherited tendencies and habits as well as environment. The old saying "pick your ancestors to live a long and healthy life" may mean that certain persons inherit a body that is more rugged and durable than the average, but it also may mean that those ancestors were physically and mentally more alert to damaging conditions and hence avoided factors that favor the occurrence of body degeneration.

Habits that tend to act adversely in the maintenance of good health are those that tend to produce anoxia of the body tissues.[7] Overindulgence in food and drink has been cited as a factor causing anoxia, as well as use of tobacco and of sedatives. Physical overactivity and mental exhaustion (stress and strain) in untrained persons may produce relative tissue anoxia and disease.

Different factors must be evaluated in geriatric medicine. Since the purpose of most medicine is primarily therapeutic, two problems arise; one concerns immediate therapy, as in most other fields of medicine, while the other is not so immediate or similar since it has to do with the application of therapeutic procedures as a preventive measure. It is necessary, therefore, that physicians understand and emphasize objectives that have to do with protection of health. It must be understood that the physiological changes that occur in the older person may lead to a disease process that must be recognized, preferably early, and treated before any immediately active medical situation can develop. It is true that most patients come to the physician with definite diseases and real complaints, such as shortness of breath or pain in the chest, and with typically degenerative body changes that have progressed to the point of disease. In these persons immediate treatment of diseases processes is indicated, but the future of the patient should be anticipated and outlined. In other words, immediate treatment only is not enough and prevention of further occurrence, if possible, should be considered.

In addition to treatment of immediate illness and adjustment of the patient to a health program for controlling an underlying disease process, a third purpose for medicine in this age group is the rehabilitation of the body during and after acute emergency. This implies, of course, that some derangement of body function exists to which a patient must be adjusted. This includes residuals after such pathological processes as intracranial hemorrhage or cardiac failure. Rehabilitation is nothing more than teaching people to live with and aiding them to develop body reserve, which is not too successful in older persons without a regimen for removing, as far as possible, the immediate cause of the ill health.

Health anticipation is of the utmost importance, therefore, and of major concern to students of this field of medicine. Total medical evaluation of the older patient is the most important factor in establishing the relation of the patient to health and implies foresight on the part of the physician in the avoidance of more or less predictable difficulties. It must be recognized that one cannot anticipate a person's health without proper diagnosis or understanding of his body function, even though the evaluation may be studious and extended.

It is necessary, therefore, that physicians learn to understand basic physiological mechanisms of older persons, even though a rather comprehensive series of diagnostic procedures may be necessary to determine the facts. It is not enough that a physical examination be done that reveals difficulty in locomotion and some arteriosclerosis, a history taken that reveals the patient is 70 and then treatment be started. In other words, proper therapy must depend on proper diagnosis. With careful study a person at or beyond middle age (40 years) in perfect health will seldom be found, because all persons have multiple, previously accumulated exhaustive processes as well as scars of prior illness that effect the clinical picture. Invariably, then, problems of older persons are relatively great, even though the individual may feel in good health. Also these problems are those of body function, may be multiple, and may be due to body tissue exhaustion as well as to reduction of tissue reserve.

The problem of medical evaluation is to recognize tissues with reduced function, particularly those pertaining to nutrition and normal body activity. It is necessary always to take complete medical and social histories as well as to make physical and laboratory studies. It is not enough to evaluate independent tissue function, but the study must be directed to an over-all study of body function as well.[8]

LABORATORY STUDIES

It is important to use the laboratory freely in geriatric medicine. Perhaps no other field of medicine requires such exacting and even "reckless" use of the laboratory. One has difficulties sometimes in hospitals in ordering "too much" laboratory work, oftentimes more than the interns and hospital staff are accustomed to, but it is the only way that early degenerative changes can be found. I want particularly to emphasize the importance of the tests of stress. Since evaluation of an older person may be similar to any type of approach where activity is important, it may be compared to evaluation of an automobile. One would not buy an unknown automobile by just listening to the motor as it idles at the curb, but would also check the tires, the battery, the functioning of the motor under conditions of stress, such as climbing a hill, and the brakes on an incline. The same principle applies in evaluating the health of an older person. Since all tissues do not wear out uniformly in all persons, it is important that individual organs and their activities also be studied when a general work-up indicates there are deficiencies. As an example, one may want to know not only the blood cell count but the rate of activity of the bone marrow and also the evidence of abnormal forms of blood cells in the blood stream. One may also want to know the rate of oxygen consumption, since there is a definite relation between some of the factors in body degeneration and this body activity.[9] The rate of radioactive iodine uptake by the thyroid gland is an index to this gland's function and is related to the rate of oxygen consumption (fig. 1). Circulation studies, checking of the size of the heart and the cardiac output, perhaps by use of the kymogram, and checking of the kidney function by the concentration diuresis test, are indicated. The measure of the venous and arterial pressure may establish certain facts about the cardiovascular system, and by roentgenography one can recognize evidence of arterial degeneration. With functional tests such as the step test and sweat test, important changes in the cardiovascular system may be recognized. The ballistocardiograph has more recently come into prominence as an important mechanism for evaluation of the cardiovascular system.

The endocrine glands play a basic part in the body disturbance in age, and studies of endocrine function are important. As has been indicated, the uptake by the thyroid gland of radioactive iodine is a factor to be considered, as are other tests that include the evaluation of the adrenal cortex by the excretion of the 17-ketosteroids, the estrogen content of the body by smears of the epithelium of the vagina or tongue, and the androgen factor by the acid phosphatase content of the prostatic fluid in a younger group. The calcium balance may indicate the rate of depletion of this substance from the body and reflect deficiency of certain of the glands.

Since nutrition is uncertain in older persons, one cannot overemphasize the importance of adequate medical guidance in this direction. Repeated glucose tolerance tests may give an idea of the carbohydrate metabolism of the older persons, which is important since many older persons tend to use carbohydrate to excess and hence to utilize it instead of other more essential substances such as protein. This test may enable a physician to advise a proper diet. Most older persons have glucose tolerance curves that do vary greatly from a recognized normal. In my experience only about 7% of persons over 40 years of age have a persistently normal curve. Our studies suggest that most older persons who have a repeated glucose tolerance curve that tends to approach normal stay healthier longer than many of those who do not. I think it wise to achieve a glucose tolerance curve as nearly normal as possible by the use of proper diet and, if necessary, by the use of insulin and other hormones if their administration seems indicated after study. The lipoprotein has more recently and rightfully come into its important place in the control of geriatric medicine. Its evaluation and proper control can be done by the electrophoresis technique or the procedures suggested by Cohn[10] and by Gofman.[11]

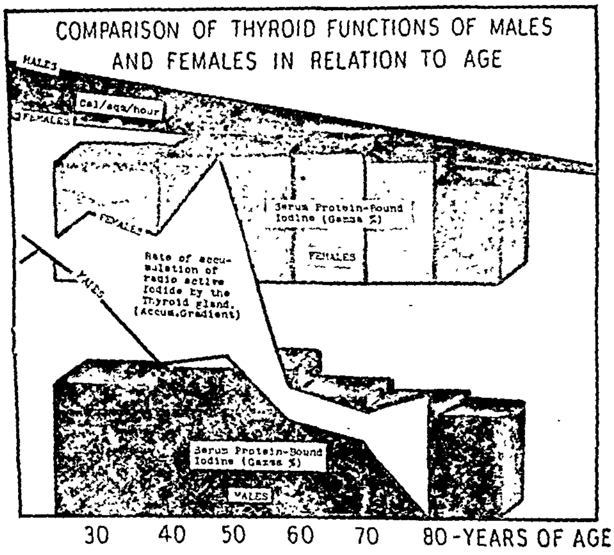

Fig. 1.—Comparison of the results of measurement of the thyroid function by three techniques. It may be noted that detail is more evident by the technique of the radioactive iodine uptake of the thyroid gland. All three tests show, but particularly the radioactive iodine uptake in most women, a tendency to maintain a relatively increased or normal thyroid function until after menopause, whereas in men even before the age of 20 the thyroid function tends to drop.

Nitrogen balance studies are very important and can be determined by measuring nitrogen intake and output over a five day period (fig. 2). Many older persons are in or tend to approach a state of negative nitrogen balance, and their protein loss may be prevented and protein restored.[12] This may be done in part with diet and the administration of proteins and hormones. Since the gastrointestinal tract plays an important part in the nutrition of any person, attempts should be made to evaluate its function if symptoms are present. Gastrointestinal roentgenograms and determination of the presence or absence of acid and enzymes in the contents may well be done. Gallbladder tests may be found necessary. The finding of various particles of undigested food in the stool permits determination of deficiencies of digestion. Most persons over 40 are in negative calcium balance, and the addition of calcium and minerals and vitamins A and D to the diet may be important. The results of calcium depletion may be readily recognized by roentgenograms after depletion is advanced. It is possible to determine the calcium balance in older persons, and this should be done in all questionable cases. The essential food substances are important in dietary regimens. Patients who have deficiencies, which, incidentally, are not generally recognized from blood studies, may have certain stigmas that help the physician to evaluate them. Vitamin A is deficient in about 15% of older persons and is characterized by skin in which the papillae stand out well against the background of the skin itself, the so-called "toad skin." Eye changes, too, may be used as a classical index to vitamin A deficiency in night blindness.

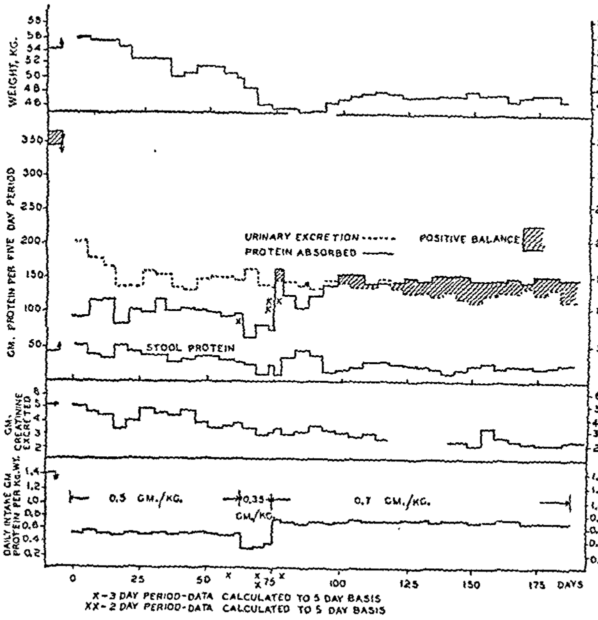

Fig. 2.—The record of a 72-year-old man who was in good health at the beginning of observation. He was in positive nitrogen balance on an unregulated diet. He was given a protein intake of different levels. Decreasing the protein level to 0.5 gm. per kilogram of body weight per day caused a negative balance, which persisted with 0.35 gm. and at which level he tended to lose weight. With 0.7 gm. he was in equilibrium most of the time. This is in contrast to most normal persons whose nitrogen balance is in equilibrium or slightly positive balance with a daily intake of 0.5 gm. of protein per kilogram of body weight.

Thiamine blood levels in 10% of older persons are lower than 2.0 mcg. per 100 cc. This deficiency is characterized by fatigue, redness and fissures of the tongue, impaired vibratory sense, and diminished reflexes. Riboflavin deficiency may be characterized by fissures in the mouth and reddened lips. Vitamin D deficiency does sometimes occur and is associated with skeletal changes. Ascorbic acid deficiency is characterized by capillary fragility, tendency to hemorrhage under the skin, and swollen and spongy gums in its later state, but early deficiency may be determined by the blood levels. Vitamin K defiicency occurs in liver and gallbladder disease, particularly in the event of disturbance of bile in the gastrointestinal tract.

DEGENERATIVE CHANGES

What, if anything, can be done about degenerative body changes has long been of concern. Some feel that the disease processes of old age are a fixed procedure, that nothing can be done once the tissues have degenerated, and that an infirm state of health must persist. Evidence that has accumulated at the Infirmary Hospital of St. Louis has definitely shown that this is not the case.[13] It has been shown that when nutritional substances such as vitamins, protein, and hormones are given in physiological amounts, the patient's disease may not progress. It has been shown further that the administration of these substances may restore a function to tissues that they formerly had and also give to certain tissues an anatomic appearance closely resembling that of an earlier age.

A word of caution should be inserted about the use of the endocrine substances, and the sex hormones are no exception. Before they are used, careful evaluation of the patient should be made. Attempts should be made to rule out conditions that contraindicate their administration. Thus, in heart disease, thyroid should be used with extreme caution, if at all. In women who have suggestions of tumor about the cervix or other conditions that might indicate cancer, careful gynecologic examination should be done before administration of the sex hormones. Also in men, the prostate should be carefully examined before and during administration of hormones, at least for a period of time. It may be unwise to give testosterone to patients who have nodules in the prostate. This substance must be administered carefully to persons who have had chronic urethritis or injury to the posterior urethra. One of the influences of androgen is to increase mucus secretions of the body, and the prostate also increases its secretion when the substance is administered. In older persons the inability of the prostate to discharge sometimes results in a swelling of the gland that, unless relieved, may cause urinary obstruction. In persons who do not have sexual intercourse prostatic massage may be instituted if testosterone must be given. Cysts in the breasts tend to develop in some women when estrogen is given. Caution should be the watchword in the administration of all hormone substances.

The important question at this time is what can be done by the average physician for the control of body degeneration. In the early stage of the occurrence of the phenomenon, say between the ages of 40 to 65 years, he can advise yearly examinations, with care taken to evaluate minor as well as major symptoms and findings. He can, in part at least, stave off anoxia of the body by controlling the rate of oxygen consumption as revealed by the basal metabolic rate. This may be done in part by the use of thyroid, iodine, and at least the B group of vitamins, and by limitation of tobacco, food, and alcohol consumption. The administration of thyroid has shown a protection of the vascular system from certain manifestations of arterial degeneration (see table).

---

[12] Kountz, W. B.; Hofstatter, L., and Ackermann, P. G.: Nitrogen Balance Studies in Four Elderly Men, J. Gerontol. 6: 20-33, 1951.

[13] Kountz, W. B.: Revitalization of Tissue and Nutrition in Older Individuals, Ann. Int. Med. 35: 1055-1067, 1951.

Faulty lipoprotein metabolism can be controlled by the administration of estrogen, the need for which may be determined by the staining reaction of the epithelium of the vagina or tongue and the zone type electrophoresis. Administration of estrogen may also lessen the load of the adrenal cortex in its adjustment during this period of life. The physician can control nitrogen loss and conserve body energy by the administration of testosterone in physiological amounts if the patient is losing nitrogen readily. He can prescribe a diet relatively high in protein, moderate in fat and carbohydrate, and particularly low in sugar if the glucose tolerance curve is persistently at variance with normal. He can determine the blood cholesterol level and, if it is above 300 mg. per 100 cc., insist that the patient lower his fat intake if it is high.

In the latter stage of degeneration after the age of 65, the physician should carry the studies further to determine the rate of oxygen consumption, the rate of iodine uptake by the thyroid gland, and the activity of the adrenal cortex by determination of the 17-ketosteroids; other tests are the insulin tolerance technique and the glucose tolerance test for the pancreas and pituitary, the calcium-phosphorus ratio and the gonadotropic substance for the anterior pituitary activity, the concentration of the urine for defects in the posterior pituitary, and other general function tests of the body. He can establish the variance of the lipotropic factor from its usual picture and attempt to adjust it by such measures as regulation of the diet and administration of hormones. Defects in any of these systems may be corrected.

NUTRITION

It must be assumed that persons past middle age have certain deficiencies, and the recognition and correction of these deficiencies is highly important. It is necessary that changes be recognized at a relatively early period of life, just as the pediatrician recognizes the changes of growth and the need for growth substances and foods, as well as immunization, in childhood. It is believed, and I feel, that strong evidence is accumulating that nutritional factors of the body past midlife are the primary concern of health in later life and that we may lift the veil of chronic illness as it is known today by paying attention to such simple factors as rate of oxygen consumption or anoxemia, endocrine balance, and the diet of persons past 40.

The diet should depend on the established physiological need of each person. A high protein intake consisting of about 1.2 gm. per kilogram of body weight is important. No sugar is advised, including any food with a degree of sweetness that will raise the blood sugar rapidly. Most vegetables and fruits are considered important. Fat in the diet is desirable, particularly with moderation, up to 80 gm. daily, depending upon the degree of overweight, if any. Addition of minerals, including calcium, phosphorus, and the trace minerals, are advised. Vitamins such as thiamine, riboflavin, and ascorbic acid are indicated to supplement the food intake in most persons.

Medical care, although it is of prime importance, is not the only factor in the control of the health of the older person. The problem of stress or adjustment of the patient to his environment is extremely important, and consultation with a physician or psychiatrist to determine the idiosyncrasies in adjustment to life's problems that sometimes are reflected in the patient's position and home activities may be necessary. From the standpoint of his occupation, it is sometimes the patient's adjustment to the ever-increasing demands of a job that may be difficult and too wearing for him that is causing difficulty. Under such conditions emotional tension and hypertension do develop. Advice by the physician to the patient and perhaps to the company for whom he works may lead to a better understanding of the problems and to better work and output with less strain. The home life problem is often quite important, and sometimes the situation is difficult to reconcile. Men and women in middle age frequently experience personality changes and problems develop that may be reflected throughout the entire family. The adjustment of this may well take the proper advice of the physician to bring about a better understanding of the persons concerned in order to remove important points of stress.

Data on Patients with Low Metabolic Rates in Follow-Up Period of Five to Seven Years*

	No. of Patients	Average Age, Yr.	Initial Average Basal Metabolic Rate	No. with Clinical Evidence of Arterial Degeneration	No. of Vascular Accidents	No. of Cardiovascular Deaths
Group 1						
Business executives, treated for more than one year	27	55	—16.5% — 6.5%	5	1 (3.7%)	0
Business executives, untreated	20	..	—16.2% —20 %	5	4 (20%)	3
Group 2						
Office patients, treated	157	63	—16.8% — 4.2%	131	9 (5.7%)	5
Office patients, untreated	42	..	—16.4% —18 %	29	10 (23%)	8
Group 3						
Infirmary Hospital, patients treated	26	67.3	—17.9% — 7 %	26	11 (42.3%)	10
Infirmary Hospital, patients untreated	16	..	—18.0% —12.0%	16	12 (75%)	12

* Each of the treated persons received a clinical dose of thyroid that was, in most instances, progressively increased. Care was taken not to produce toxic manifestations, but an attempt was made to raise and maintain the basal metabolic rate at as near normal as possible.

Physical activity and rehabilitation are also important. Encouraging individuals to be active physically leads also to mental activity. Interest in one's environment and realization that he is an important factor in society, particularly with those whom he holds dear, are stimulating adjuncts to the health of the older person. Since the secret of both physical activity and mental alertness lies in the maintenance of good health, however, the medical aspect of this problem is far more important than any other in the field.

SUMMARY

Factors concerned in geriatric medicine are discussed that have been found to apply in the research laboratory as well as in private practice. The study of an older person must consist of an over-all evaluation of the patient, with particular tests of individual organs as well as of the over-all function of the body. It has been established that medical control of diseases that develop in the older person is of primary importance in the maintenance of health but that adjustment of the person to his environment and a feeling of importance in his social relationships assist in the program.

5600 Arsenal St. (9).

GROSS URINARY HEMORRHAGE: A SYMPTOM, NOT A DISEASE

Leroy W. Lee, M.D.
and
Edwin Davis Jr., M.D., Omaha

Gross urinary hemorrhage is a common symptom usually indicating urinary tract disease. The term hematuria is most frequently used to describe the finding of blood in the urine, but unfortunately it is too often considered a diagnosis in itself. The symptom of blood in the urine is frequently passed over by patient and physician alike without much concern. In most instances the bleeding subsides spontaneously and is forgotten until another episode occurs. When a patient comes for consultation because of painless bleeding, it is often difficult for the physician to insist on a complete urologic examination. Pain is not often a concurrent symptom in the most serious urinary diseases giving rise to bleeding. If patients realized how many persons die or have long periods of hospitalization because they waited for a second or third episode of bleeding before seeking special care, they would insist on immediate and complete urologic study.

TABLE 1.—*Causes of Hematuria*

  - Calculus
  - Tuberculosis
  - Other infections
  - Foreign body
  - Stricture
  - Hydroureter
  - Periureteral lesions
  - Ureteritis cystica

There is no more important single painless warning signal of disease than gross urinary hemorrhage, and it demands immediate urologic study to determine the cause and localization as soon as possible after onset. Cystoscopy is basic, and, if necessary, urethroscopic examination or ureteral catheterization and retrograde pyelography should be done. Blood appearing at the meatus or at the beginning of urination is usually from the urethra distal to the external sphincter. Blood from the prostatic urethra above the external sphincter (with respect to urination) is frequently terminal. Blood from the bladder or the upper urinary tract uniformly colors the entire urine sample. Pain in a ureteral distribution associated with clots and blood in the urine sometimes suggests which side is the source of bleeding.

In general, causes of urinary bleeding may be divided into three classes: intrinsic urinary lesions, lesions of the adjacent organs, and complications of a medical or systemic disease (table 1). The first group is the one with which the urologist is primarily concerned, but an intrinsic urinary lesion should be diagnosed or ruled out early in the study of any patient with hematuria.

Recently we reviewed the records of 1,000 consecutive patients with the symptom of gross urinary hemorrhage. Patients ranged in age between 5 and 94, but most of them were between 50 and 80. The age distribution of patients by decades is shown below:

0-9	20	50-59	204
10-19	25	60-69	222
20-29	103	70-79	134
30-39	115	80-89	31
40-49	144	90-99	2

Of the 1,000 patients there were 666 males and 334 females, a ratio of 2 to 1. The time elapsing between the first occurrence of gross urinary hemorrhage and the patient's consultation of a urologist varied from a few hours to as long as two years, as seen in the following figures.

1-6 days	303	6-11 months	85
7-30 days	233	11-18 months	71
1-5 months	193	Over 18 months	115

The number of patients in whom various symptoms associated with gross urinary hemorrhage occurred are listed. In approximately one-fifth of the patients the bleeding was not associated with pain or any other symptom.

None	168
Cystic symptoms	370
Vesical neck obstructive symptoms	156
Upper urinary tract pain	273
Urethral pain	3
Urethral discharge	5
Blood dyscrasia	5

From the Department of Urology, University of Nebraska College of Medicine, and University, Clarkson, and Lutheran hospitals.

Methods of study used to establish a diagnosis of cause and localization of source of gross urinary bleeding follow.

Cystoscopy alone	468
Cystoscopy and retrograde pyelography	517
Others: kidney, ureter, and bladder film alone	10
Intravenous urography	59
Urethral instrumentation	15
Urethral smear	5
Blood study	5

In approximately one-half of the patients it was possible to establish a diagnosis (table 2) from the findings of simple office cystoscopy or other office procedures. The other patients required complete hospital study including cystoscopic examination, ureteral catheterization, and retrograde pyelography.

Table 2.—*Diagnosis in 1,000 Patients with Gross Hematuria*

	No. of Patients
Kidney	
Tumor	35
Pyelonephritis	30
Calculus	27
Trauma	20
Hydronephrosis	15
Polycystic disease	6
Chronic glomerulonephritis	6
Ptosis	4
Cyst	3
Hemorrhagic papillitis	3
Infarct	1
Malignant nephrosclerosis	1
"Sulfa" block	1
Ureter	
Calculus	53
Tumor	7
Stricture	4
Ureteritis cystica	1
Bladder	
Cystitis	220
Tumor	149
Calculus	12
Hunner's ulcer	4
Diverticulum	3
Secondary carcinoma	3
Trauma	2
Cystitis cystica	1
Varix	1
Prostate	
Benign hyperplasia	125
Chronic prostatitis	90
Carcinoma	21
Urethra	
Stricture	17
Calculus	13
Tumor	3
Rupture	3
Foreign body	1
Trauma	1
Diverticulum	1
Gonorrhea	4
Urinary infection (general)	12
Urinary tuberculosis	7
Essential hematuria	85
Systemic causes	
Hemophilia	2
Thrombocytopenia	1
Uremic syndrome	1
Bishydroxycoumarin (Dicumarol) poisoning	1

In approximately 8% of the patients no cause for the bleeding was found. These cases are classified as essential hematuria. Further study at subsequent periods of bleeding often clarifies diagnosis in such patients. The organ source of bleeding and the basic pathological conditions that gave rise to hematuria are listed below.

Kidney	152
Ureter	65
Bladder	395
Prostate	236
Urethra	43
General involvement	19
Systemic diseases	5
Essential hematuria	85

Infection	369
Tumor	218
Obstruction	161
Calculus	105
Trauma	26
Congenital anomaly	18
Foreign body	1
Medical causes	17
"Essential" hematuria	85

The methods of treatment of these 1,000 patients were:

No treatment	237
Systemic antibiotics and antiseptics alone	51
Kidney	
Lumbar nephrectomy	43
Transperitoneal nephrectomy	12
Pelviolithotomy	9
Pelvioplasty	2
Ureter	
Cystoscopic manipulation	16
Ureterolithotomy	10
Nephroureterectomy	6
Bilateral ureterosigmoidostomy	4
Transurethral endovesical ureterolithotomy	3
Nephroureterectomy, cystectomy and ureterosigmoidostomy	2
Ureterovesiconeostomy	1
Bladder	
Merbromin (Mercurochrome) instillations	217
Silver nitrate instillations	4
Transurethral fulguration or resection	53
Suprapubic cystostomy	25
Suprapubic cystostomy, segmental resection	15
Suprapubic cystostomy, electrosurgical resection and fulguration	33
Bilateral ureterosigmoidostomy and cystectomy	14
Litholapaxy	5
Prostate	
Massage	90
Perineal prostatectomy	66
Total perineal prostatectomy	2
Transurethral prostatectomy	41
Transurethral prostatectomy and bilateral orchiectomy	12
Suprapubic prostatectomy	5
Urethra	
Internal urethrotomy	5
Urethral instrumentation	11
Plastic repair	2
Excision diverticulum	1
Meatotomy	3

REPORT OF CASES

Case 1.—A 36-year-old physician complained of gross urinary hemorrhage with clots of four days' duration and associated right loin pain. Physical examination revealed a right loin mass, and retrograde pyelography showed a mass lesion of the right kidney. On surgical exploration an inoperable adenocarcinoma of the kidney that had already invaded the renal vein was found. The patient died within a few days. This situation illustrates the advanced state of disease that may exist in the urinary tract before the symptom of gross urinary hemorrhage appears.

Case 2.—A 52-year-old man had gross urinary hemorrhage of only six days' duration. Cystoscopy revealed a neoplasm in the bladder. Suprapubic operation showed an inoperable infiltrating carcinoma of the bladder invading the bladder wall and paravesical tissues. This was also a case of advanced disease before the appearance of urinary hemorrhage.

Case 3.—A 52-year-old man had had frequent intermittent, gross urinary hemorrhage with clots for five years. He had been studied elsewhere three years previously, and no cause had been found. Cystoscopy revealed a large papillary carcinoma of the bladder. The tumor had a pedicle. Suprapubic approach was made, and a tumor the size of a tennis ball was excised by the electrosurgical method. There has been no recurrence in seven years. In some instances, a patient may have hematuria over a long period and still benefit from surgery.

Case 4.—A 51-year-old man had a history of intermittent hematuria of two years' duration, nocturia of four to six years' duration (frequency of every hour), difficulty in starting, and a scant stream for one year. He was admitted to the hospital with acute urinary retention of 12 hours' duration. The patient had consulted several physicians during this time and had been treated with various medicaments without effect. Urologic consultation had not been advised by any of these physicians. Cystoscopy showed a papillary carcinoma of the bladder. Suprapubic operation was done and an extensive inoperable, infiltrating carcinoma of the bladder was found. He was dismissed from the hospital with a permanent suprapubic cystostomy tube in place, as the condition was hopeless. This patient is typical of the medically neglected patient with gross urinary hemorrhage.

SUMMARY

Gross urinary hemorrhage is a common symptom directing attention to the urinary tract. Immediate urologic study is imperative in every patient showing gross urinary hemorrhage. Whether or not associated with pain, gross urinary hemorrhage should be considered indicative of a serious urinary lesion until proved otherwise. In this series of 1,000 patients 22% had carcinoma in the urinary tract.

NEUROSURGICAL TREATMENT OF COMPRESSION OF THE SPINAL CORD CAUSED BY MYELOMA

Hendrick J. Svien, M.D., Richard D. Price, M.D.
and
Edwin D. Bayrd, M.D., Rochester, Minn.

Our interest in neurosurgical treatment of compression of the spinal cord caused by myeloma was stimulated by the observation of three such cases within a relatively short time. Laminectomy, decompression, and partial removal of the compressing myeloma were done in each instance. Gratifying clinical results were obtained in two of these cases despite the presence of extensive disease and great loss of function prior to operation; therefore, it was thought that a review of experience with this condition at the Mayo Clinic would call attention to the possible value of palliative operations.

REVIEW OF THE LITERATURE

Cases of myelomatous compression of the spinal cord in which relief was obtained by laminectomy and decompression, with or without subsequent roentgen therapy, have been reported. Jacox and Kahn [1] reviewed the literature and found three instances in which laminectomy and decompression had been performed. Klemme [2] reported his experience in five cases; in three of these, presumed to be due to solitary myeloma, good results had been obtained for three years, seven months, and six months, respectively, at the time of the report. In one case, an instance of multiple myeloma, satisfactory results had been maintained for 14 months at the time of the report. Postoperative roentgen therapy was used in all of Klemme's cases. Denker and Brock [3] reported two cases of localized vertebral myeloma with compression of the spinal cord. After laminectomy and decompression there was good clinical recovery; in one case this lasted for two years, in the other for nine months. Roentgen therapy was given in both instances. Wright [4] reported a case in which solitary plasma cell myeloma of a vertebral body had caused paraplegia. Laminectomy and implantation of radon seeds resulted in such improvement that the patient was walking normally one year later.

Paul and Pohle [5] reported three cases of compression of the spinal cord caused by solitary myeloma. Roentgen therapy was given after laminectomy and decompression. In one case, improvement was noted for 11 months, after which the condition became worse; symptomatic improvement was seen in another case for 16 months although roentgenographic evidence of extension was present; in the third case, rehabilitation was complete 9 months after operation. Snyder and Wilhelm [6] reported "spectacular disappearance of associated neurologic findings following laminectomy in a 49-year-old patient with paraplegia of four weeks' duration due to multiple myeloma." The patient walked unaided a month after operation; neurological examination four months later showed no abnormal findings. Postoperative roentgen therapy was given in this case.

REPORT OF CASES

A review of the cases in which the diagnosis of myeloma was made at the Mayo Clinic from 1930 to 1950 inclusive revealed that 31 (6%) of the 524 patients in which this diagnosis was made were paraplegic when examined. Laminectomy and decompression were done in 7 of these 31 patients.

CASE 1.—A 58-year-old white woman came to the clinic on Nov. 5, 1946. For about a year she had experienced pain in the midthoracic region. The pain progressed, and her physician made a diagnosis of neuritis. The pain steadily became more intense, and during the last six months she had noticed weakness in her legs and soon needed support in walking. One month prior to admission she had noticed incontinence and numbness in her legs.

General physical examination disclosed no important abnormalities except the neurological changes, which included moderate weakness of the lower extremities below the level of the 12th thoracic segment, diminished sensory perception below the level of the 10th thoracic segment, and incontinence of feces and urine. Laboratory examination yielded values within normal limits for hemoglobin, erythrocytes, and leukocytes. Serum protein was 6.3 gm. per 100 cc.; the albumin-globulin ratio was 1.5:1. Roentgenologic examination of the thoracic portion of the spinal column revealed osteoporosis of the body of the eighth thoracic vertebra. A diagnosis of compression of the spinal cord caused by either a primary malignant vertebral lesion or metastatic carcinoma was made. Myelography by means of ethyl iodophenylundecylate (Panto-

paque) showed complete obstruction of the cephalad flow of the medium at the upper margin of the ninth thoracic vertebra. Protein content of the cerebrospinal fluid was 80 mg. per 100 cc.

On Nov. 19, 1946, laminectomy was performed at the level of the eighth and ninth thoracic vertebrae. Reddish-brown, friable vascular tissue was found completely encircling and compressing the spinal cord extradurally. Biopsy revealed the tissue to be a plasma cell myeloma. As much of the tissue as possible was removed, and the wound was closed. When the patient was dismissed from the hospital on the 17th postoperative day, she had no pain and had regained some strength in her legs. A course of roentgen therapy was given. In May, 1948, 18 months after operation, she was free of pain, walked normally, and had no incontinence. In a follow-up study 63 months after operation, she stated that she was able to walk normally and do her housework; she was free of pain and had normal sphincter control.

Case 2.—A 42-year-old white man entered the clinic on Nov. 1, 1949, complaining of back pain of five months' duration. In July, 1949, he had undergone an operation for a protruded fourth lumbar disk. He came to the clinic for examination because of persistent pain. Roentgenologic examination revealed a destructive lesion in the body of the first lumbar vertebra. Myeloma and Ewing's tumor were considered in the differential diagnosis. During examination, the patient experienced intense pain in his back when he stooped over; progressive paraplegia developed within the next few days.

Data on Seven Patients with Compression of the Spinal Cord Produced by Myeloma

Case No.	Myeloma	Erythrocytes, Millions	Leukocytes	Hemoglobin, Gm. (Photoelectric Method)	Skeletal Roentgenographic Findings	Method of Diagnosis	Date of Operation	Comment
1	Solitary	4.44	8,600	12.3	Lesion in the 8th thoracic vertebra	Biopsy	11/19/46	Good results; roentgenograms in 1950 showed multiple myeloma; Bence Jones protein in urine
2	Multiple	4.56	6,200	13.9	Lesion in the 1st lumbar vertebra	Biopsy Sternal aspiration	11/14/49	Returned to work; died in June, 1951
3	Multiple	5.28	2,500	15.5	Lesion in the 4th, 5th, and 6th thoracic vertebra	Biopsy Sternal aspiration	3/ 2/50	Good results
4	Multiple	3.59	6,100	11.0	Lesion in the 4th thoracic vertebra	Biopsy Sternal aspiration	9/ 7/50	No relief; died 9 months after operation
5	Solitary?	4.21	9,000	15.2	Lesion in the 2nd thoracic vertebra, contiguous soft tissue, and transverse process	Biopsy	7/20/34	Only slight improvement; died in October, 1935
6	Solitary?	....	11,900	16.1	Lesion in the 7th thoracic vertebra and contiguous soft tissue	Biopsy	7/ 4/42	No improvement; died January, 1944
7	Solitary	4.57	6,100	13.6	Lesion in the 5th thoracic vertebra	Biopsy	12/10/30 3/ ?/32	Good results; died May, 1938

Emergency laminectomy at the level of the first lumbar vertebra was done on Nov. 14, 1949, at which time the patient was almost completely paralyzed from the hips down and was incontinent. Subtotal removal of a myeloma and decompression of the spinal cord were done. The cortex of the vertebra posteriorly was fractured and displaced into the intraspinal space, with extensive compression of the dural sac. The root of the first lumbar nerve on the right side was sectioned extradurally to permit mobilization of the spinal cord and removal of the fractured cortical bone.

The diagnosis of multiple myeloma was made postoperatively by studies of bone marrow. Administration of urethan was begun. The patient was dismissed from the hospital on the 36th postoperative day, at which time he was on crutches and wearing a back brace. Within three months he was able to walk without support and soon returned to work. In November, 1950, one year after operation, he suffered a spontaneous fracture of the right humerus; however, he was again able to return to work. In May, 1951, he began to fail rapidly and died in June, 1951, 19 months after operation.

Case 3.—A 65-year-old white man came to the clinic on Feb. 26, 1950. He had noticed weakness of his legs in October, 1949, and two weeks prior to admission he could no longer walk. The patient was totally paraplegic and incontinent. Sensory loss was complete below the level of the fifth thoracic dermatome. Roentgenologic examination revealed collapse of the fourth thoracic vertebra and erosion of the pedicles of the fifth and sixth thoracic vertebrae. The diagnosis was that of a malignant lesion of the vertebrae, probably primary, with intraspinal extension. Results of hematological studies were within normal limits except for a leukocyte count of 2,500 per cubic millimeter of blood. Serum protein was 5.6 gm. per 100 cc., and the albumin-globulin ratio was 2:1. Results of urinalysis, including tests for albumin and Bence Jones protein, disclosed no abnormalities.

Laminectomy and decompression of the spinal cord were performed on March 2, 1950. Biopsy revealed a myeloma. Reddish-brown, friable vascular tissue completely encircled the extradural aspect of the spinal cord. Subtotal removal of this tissue was done, with extradural bilateral rhizotomy of the fifth and sixth thoracic nerves. At the conclusion of these procedures, the spinal cord appeared to be well decompressed, and pulsations of the dura were noted. Postoperatively, the diagnosis of multiple myeloma was made by studies of bone marrow. The patient received roentgen therapy and urethan during convalescence. At discharge on May 14, 1950, he was able to walk with the aid of crutches. His back was supported by a brace. Improvement continued, and within several months he was able to walk normally and had regained sphincter control. At a follow-up examination 24 months after operation he had good sphincter control, was able to walk normally, and considered himself in good health.

Case 4.—A 64-year-old white woman was admitted to the clinic on Sept. 1, 1950. She had been hospitalized elsewhere because of the possibility of tuberculosis; however, no bacteriological evidence of the disease had been obtained. On Aug. 18, 1950, after an attack of coughing, the patient experienced pain in the upper part of the thoracic region, followed by slowly progressive numbness in both legs; within five days, loss of sensation extended to the nipple line. She was completely paraplegic and had no sphincter control. Neurological examination showed flaccid paraplegia with complete loss of sensation below the level of the fourth thoracic segment and incontinence. On roentgenologic examination an irregular mass in the upper right lung and a compression fracture of the fourth thoracic vertebra were seen. Serum protein was 7.6 gm. per 100 cc., with an albumin-globulin ratio of 1:1.2; absolute values for albumin and globulin were 3.4 and 4.2 gm. per 100 cc. respectively. Results of urinalysis were normal. A preoperative diagnosis of a metastatic lesion of the fourth thoracic vertebra with compression of the cord was made.

On Sept. 7, 1950, laminectomy at the level of the fourth and fifth thoracic vertebrae was done. Reddish-brown, friabl vascular neoplastic tissue filled the intraspinal space and completely encircled the spinal cord. Biopsy identified the tissue as a plasma cell myeloma. As much of the tumor as possible was removed. In order to provide further decompression of the spinal cord, the third and fourth thoracic nerves on the right side were sectioned extradurally. The dura was then seen to pulsate, which had not been noted previously. Diagnosis of multiple myeloma was made postoperatively by studies of bone marrow. Bence Jones proteinuria was found. The patient received urethan and roentgen therapy. No change was noted in the neurological status when she was discharged. Her condition gradually became worse, and she died nine months after operation.

Case 5.—A 40-year-old white man came to the clinic on July 4, 1934, with progressive loss of sensation in the legs of six months' duration and paraplegia of five months' duration. Neurological examination disclosed transverse myelitis at the level of the second thoracic segment. Results of hematological examinations and urinalysis were within normal limits. Roentgenologic examination of the thoracic part of the spinal column revealed a destructive process of the second thoracic vertebra. The preoperative impression was that of a primary tumor of the spinal cord.

Laminectomy was done on July 20, 1934, at which time partial removal of an extradural myeloma and decompression of the spinal cord were accomplished. No change in the neurological status was seen postoperatively. Roentgen therapy was given. The patient died 16 months after operation, which had effected only slight improvement in the strength of his legs.

Case 6.—A 49-year-old white man entered the clinic on June 16, 1942. He had been well until 1940, when he noted pain in the upper part of the thoracic region, and in December, 1941, he had experienced difficulty in walking. Paraplegia and incontinence had appeared seven weeks prior to admission. Neurological examination disclosed paraplegia from the 12th thoracic segment down, loss of sensation from the 10th thoracic segment down, and incontinence. Hematological examinations disclosed no abnormalities. Results of urinalysis were within normal limits except for a small amount of albumin (1+). A compression fracture of the seventh thoracic vertebra was found on roentgenologic examination. The preoperative impression was that of a metastatic tumor.

Laminectomy at the level of the seventh thoracic vertebra was performed on July 4, 1942. An extradural, reddish-brown neoplasm encircled the spinal cord. The tissue was found to be myeloma on biopsy. Subtotal removal was done. No change in the patient's neurological status was noted postoperatively. Roentgen therapy was given. The patient died 18 months after operation, having received no benefit from decompression of the spinal cord.

Case 7.—A 38-year-old white man was admitted to the clinic on Dec. 2, 1930, with a history of back pain of one year's duration. One week before admission he had suddenly become paraplegic. Neurological examination showed paraplegia, incontinence, and hypesthesia from the level of the fifth thoracic segment down. Hematological studies disclosed no abnormalities; urinalysis revealed a moderate amount of albumin (2+). Roentgenograms showed destruction of the body of the fifth thoracic vertebra. A metastatic tumor was suspected.

On Dec. 10, 1930, laminectomy disclosed a friable, vascular neoplasm encircling the spinal cord; biopsy revealed the lesion to be a myeloma. Subtotal removal was done. Extradural section of the fifth and sixth thoracic nerves was performed bilaterally to facilitate further decompression of the cord. Roentgen therapy was given several times postoperatively. Within a few weeks the patient was ambulant, was free of pain, had good sphincter control, and had returned to work. Recurrence of the signs and symptoms of compression of the spinal cord occurred in January, 1932, and the patient was operated on elsewhere in March, 1932. He again returned to work until 1938, when his general health failed and he died.

SUMMARY AND CONCLUSIONS

The table presents a summary of these seven cases. Gratifying results were obtained in four cases, and the patients were well and ambulant for 84, 63, 24, and 19 months respectively. In all our cases and in most of the cases in the literature, the osseous defects were solitary or were limited to contiguous areas. The excellent results obtained by Snyder and Wilhelm[6] indicate that patients who have multiple myeloma respond as well to laminectomy and decompression as do patients who have localized myeloma, the limiting factor being the inherent difference in the ultimate prognosis in the two conditions.

In none of our cases was the diagnosis of myeloma made preoperatively. The diagnosis in each case was compression of the spinal cord of indeterminate origin. Among the conditions considered were metastatic carcinoma, tuberculosis of the vertebrae, Ewing's tumor, and primary neoplasm of the vertebrae. Thus, it would appear that patients with compression of the spinal cord as a result of myeloma, either solitary or multiple, should be given the benefit of palliative operative procedures. Even though the lesions are strongly suspected of being metastatic, the neurosurgeon should offer palliation unless laminectomy and decompression clearly are contraindicated. In a gratifying number of cases the results of such surgical therapy are rewarding.

Anesthesia in Cardiac Disease.—First principle to be observed in the presence of heart disease is the necessity for adequate oxygenation, and this implies two different processes. First, the patient must receive considerably more oxygen than is contained in the atmosphere; and the worse the cardiac condition the greater the percentage of oxygen must be in the inspired mixture. Therefore nitrous oxygen should play little, if any, part in anesthesia for really severe cases of heart disease. Secondly, the patient's oxygen requirements should be diminished by adequate premedication and the establishment of metabolic conditions as close as possible to basal. . . . The old view that the use of depressant drugs should always be avoided in the presence of heart disease is quite wrong. Rather is it essential that emotional disturbances should be minimal, as these may precipitate an attack of angina in patients with coronary disease, or pulmonary edema in patients with mitral stenosis. Therefore even after ample premedication it is necessary to induce anesthesia by the intravenous rather than the inhalational route. . . . Cardiac patients need smaller doses of all anesthetic drugs than do healthy individuals. . . . To avoid hypoxia during administration, it is altogether essential to avoid any form or degree of respiratory obstruction; the most important single step to this end is preliminary topical anesthetization of the larynx. . . . If it is not considered necessary to intubate in a particular case, anesthetization of the larynx is even more useful as it abolishes all possibility of laryngeal spasm, and in itself almost completely ensures a smooth administration. . . . After the avoidance of anoxia, the next most important point is the preservation of an adequate blood pressure. Cardiac patients have very little ability to increase their cardiac output in response to peripheral vasodilatation, and they stand fall of blood pressure badly, and this may lead to coronary or cerebral insufficiency. DECUBITUS ULCERS TREATED WITH DRIED BLOOD PLASMA

PRELIMINARY REPORT

A. Bernice Clark, M.D.
and
Howard A. Rusk, M.D., New York

Over the past 30 years, there have been some 40 reports in the literature on the therapy of decubitus ulcers covering a multitude of treatments with ointments, pastes and solutions, insulin [1] and blood transfusion.[2] Most of the latest references concern surgical treatment and the use of streptokinase and streptodornase [3] as an adjunct to surgical closure.

In 1946 a study was made on 80 paraplegic patients with decubitus ulcers in the Newton D. Baker Hospital in Martinsburg, W. Va., by Barker and co-workers,[4] who hypothesized that the ulcers themselves established a vicious circle and contributed to the patient's general debility. One patient was found to have lost 50 gm. of protein in 24 hours from five ulcers. The conclusion of this study was that surgical closure was the therapy of choice. This conclusion seems justified unless a more conservative but effective method of healing can be found that will prevent plasma loss and the debilitating phenomena.

The specific cause of decubitus ulcers has not been established. The pathogenesis of induced decubitus ulcers in rabbits was studied by Groth [5] in 1942. In this study, ulcers were developed by exerting pressure over the gluteal region. The amount and time of pressure was varied. The animals were killed at various stages, and the lesions were examined microscopically and macroscopically to determine the effects of pressure. These studies suggested that there was some correlation between weight, pressure, and time of exposure of an animal in the formation of a decubitus ulcer. Their findings suggested mechanical factors as a primary cause of such ulcers.

Malnutrition has long been recognized as a definite deterrent to healing. Assuming the cause of decubitus ulcers, or at least a major contributing factor, to be ischemia and, consequently, poor nutrition to the part, and in view of the general factors of malnutrition, it would seem logical to expose the cells to as natural a nutritional environment as possible in order to promote more rapid healing. Plasma appeared to be a logical substance to provide such an environment. A clinical study was started on this premise.

The purpose of this report is to present preliminary observations made over the past 14 months of decubitus ulcers in patients with spinal cord injuries, treated with a paste consisting of dried blood plasma and Peruvian balsam. A controlled experiment was difficult owing to the difficulty of finding paired lesions. The results of treatment in this series have been evaluated on the basis of scar tissue type and rapidity of healing as compared with these factors in other lesions for which some other therapy was used.

MATERIALS AND METHODS

Selection of Patients.—Eleven patients were included in this study. All had normal blood and blood chemistry findings. Five of the patients had lesions that were deeply undermined. Patients with underlying osteomyelitis were not considered suitable for the study.

Method of Application.—The vehicle selected for the plasma was Peruvian balsam because of its mild antiseptic action and its well-established place in the treatment of wounds. A quantity sufficient to make the plasma into a very thick paste was used. The paste was packed into the ulcer and covered with a single layer of sterile gauze. A piece of oiled silk or other moisture-proof material, slightly larger than the gauze, was placed over the single layer of gauze, and the area was then sealed with elastic adhesive tape. Protective dressings were placed over this to absorb any possible seepage. The dressings were ordinarily left undisturbed for three days and changed on the fourth day. A fresh paste was made for each dressing.

Observations.—The rapidity of granulation and healing was striking in all instances and was especially noted in those ulcers in which there was necrosis and infection, where the débriding action of the paste was most significant. One long-standing ulcer with considerable necrosis complicated by a pyocyanic infection was clean after the third dressing (12 days), and an excellent bed of granulation was established.

In all instances, rapid growth of granulation tissue was noted after the third or fourth application. Bleeding occurred occasionally. In one case only, the treatment was discontinued because of frank bleeding after application of the paste. The growth of tissue became so profuse in some instances that discontinuation of therapy was considered; however, it was noted that with continuing treatment the granulations reached a plateau and then were literally tucked in by the progression of the epithelium. Epithelial growth was slow until the ulcer was filled with clean granulation. The least responsive type of ulcer was that in which firm scar tissue had

already formed. In the ulcers without scar tissue, the new epithelium more closely approximated normal skin rather than the thin type usually covering the scarified area.

While receiving this type of conservative treatment the patients were able to be on a partial program of active rehabilitation training that (*a*) minimized the possibility of the development of renal calculi; (*b*) reduced the tendency to greater osteoporosis; (*c*) helped in general to maintain the normal metabolic processes; and (*d*) maintained a high level of morale in the patient. In complete paraplegia, with both paralysis and anesthesia, there was obviously no pain problem; however, a number of patients with partial paralysis with pain sensation intact complained bitterly of burning from the paste. This burning was obviated by the use of powdered plasma, without the Peruvian balsam. There was no instance of homologous serum jaundice in these patients treated with the local application of dried blood plasma.

COMMENT

This report is based entirely on clinical observation. The difficulty of a control series has been stated. The clinical observations, however, have so impressed us that we have enlarged our working hypothesis beyond the beneficial environmental role of dried plasma. With the dissolution of necrotic tissue and the rapidity with which the wounds were débrided, it might be assumed that the dried plasma contains a protease that becomes activated. This would explain the accelerated débridement resulting in a more promising and normal cellular environment for new granulation tissue. We have used the dried plasma up to this time only on decubitus ulcers, but it is hoped that it may prove beneficial in other types of indolent ulcers. Laboratory studies are now in progress to give an objective basis for use of this therapy in this type of ulcer and to substantiate the clinical findings. For these studies, dried plasma alone without Peruvian balsam is being used.

SUMMARY

Clinical observation was made of decubitus ulcers treated with dried human blood plasma. From this study, it was noted that with local application of the dried plasma there was a débriding effect on necrotic and infected tissue and rapid granulation followed by acceleration of epithelial coverage. In preliminary observations, there is some presumptive evidence of proteolytic activity in dried plasma.

SHOULDER-HAND SYNDROME

SYMPATHETIC BLOCK COMPARED WITH CORTICOTROPIN AND CORTISONE THERAPY

Otto Steinbrocker, M.D., David Neustadt, M.D., New York
and
Lyon Lapin, M.D., Montreal, Canada

It is the purpose of this paper to compare the effects of cortisone and corticotropin (ACTH) with those of stellate blocks in management of the shoulder-hand syndrome (reflex dystrophy of the upper extremity). Owing to the present lack of such comparative information on these methods of treatment, we wish to present our observations. The concept of the shoulder-hand syndrome has been widely discussed in previous publications.[1]

TREATMENT OF SHOULDER-HAND SYNDROME

Many forms of therapy have been attempted with largely unsatisfactory results. Our observations, like those of others, had led us to regard sympathetic ganglion block with procaine, or similar substances, as the most beneficial nonsurgical treatment for the shoulder-hand syndrome.[2] To date, of 126 cases of this entity under our observation, 69 have been treated by stellate blocks. Complete recovery or great improvement occurred in 22 patients (31.8%), 34 (49.3%) have received appreciable benefit, and 13 (18.9%) had no response.

With the advent of corticotropin and cortisone, it seemed desirable to investigate the action of these agents in reflex dystrophy. In spite of the voluminous literature relating to corticotropin, cortisone, and other steroids, few references are made to their use in this disorder, apart from our own initial report.[1m] It probably is relevant to mention here that from our observations of untreated patients it seems clear that a natural recovery from pain and disability is apt to occur more rapidly at the shoulder than at the hand and fingers. The effect on the hand, with regard to pain, tenderness, swelling, limited flexion and extension, muscular atrophy, cutaneous atrophy, and vasomotor disturbances and contractures with their more likely irreversible and disabling alterations, constitutes a critical measure of the usefulness of any therapeutic agent or procedure in this condition.

SYMPATHETIC BLOCK

In the 69 cases so treated, the stellate ganglion was injected by the anterior (paratracheal) approach. An injection of 10 cc. of 0.5% procaine hydrochloride solution, or its equivalent, was used for the initial infiltration. Thereafter 20 cc. of 1% solution was the usual amount

until a satisfactory response was produced or until four to five blocks had shown no effect. Table 1 gives the data on 14 consecutive patients with reflex dystrophy of the upper extremity treated with sympathetic blocks that are representative of our experience with this procedure in 69 cases.

Of these 14 patients, 7 were in phase 1, 2 were in phase 2, and 5 were in phase 3. Phase 1 was defined as the period of painful shoulder dysfunction, painful swelling of the hand and digits on the same side, and, usually, increased surface temperature and vasodilation; phase 2, the period of gradual resolution of those features seen in phase 1, with the appearance of early trophic changes, onset of vasospasm, and coldness of the hand and fingers; and phase 3, the period of trophic changes, such as atrophies, contractures, deformities, and other irreversible changes. Table 2 shows the results according to the phase of the disease at the time treatment was started. In phases 1 and 2 recovery of shoulder function was almost invariably accomplished, while in phase 3 the result was poor. In phase 1 hand signs were eliminated in all but one instance, whereas in phases 2 and 3 relief was chiefly from pain; there was but little influence on the trophic changes and disability of the hand. Complete relief of shoulder pain was obtained in all but one case. Hand pain was completely relieved in all except 1 patient.

TABLE 1.—*Results in Fourteen Patients with Shoulder-Hand Syndrome Treated by Stellate Ganglion Block*

Hand pain............	5	5	0	0	0
Hand signs...........	5	0	1	2	2

In the early phases of the condition, swelling and vasomotor disturbances of the hand decreased after sympathetic blocks.

No rigid routine was established for the treatment of these patients. We administered 1 to 14 stellate blocks at two to seven day intervals on an ambulatory basis. In the majority of the patients seven injections or less were required. Whether the recently instituted continuous sympathetic block done in the hospital provides better results has not been determined. The anterior (paratracheal) stellate block is the safest technique and is comparatively free from complications. In seven years the complications were a small hematoma that occurred during the residual effect of previous anticoagulants and a pneumothorax probably not fairly attributable to the technique. Minor and transient reactions, arising from procaine, needle punctures, or anxiety, appeared in about 20% of the patients but did not interfere with continuation of the procedure.

CORTICOTROPIN AND CORTISONE

To date we have treated 13 cases of complete shoulder-hand syndrome with corticotropin and cortisone or both. This study was based on a series of patients who were followed up long enough to permit comparison of results of hormone therapy with those of stellate blocks, within the limitations of such small series. The two groups were comparable as to sex, duration of symptoms, and etiology.

Of those receiving corticotropin and/or cortisone, two patients were in phase 1, seven were in phase 2, and four were in phase 3. Table 3 gives an analysis of the results. In table 4, the outcome is summarized according to the phase of the disease. In four of these patients there was bilateral shoulder-hand involvement. Five patients were treated with corticotropin, seven with cortisone, and one with both hormones consecutively. Previous treatment included physiotherapy, alcohol-iodine injections periarticularly into "trigger-points," analgesics orally, and stellate ganglion blocks. These measures had afforded only transient, slight relief in some of the patients.

All symptoms and signs were abolished in four patients, and great improvement (almost complete resolution) occurred in four others. One patient failed to respond; however, he had hypertensive cardiovascular disease and had suffered a cerebral accident. For these reasons he was given small doses of corticotropin (25 mg. daily) for only one week. Although larger amounts might have been more effective, the general condition of the patient was such that further therapy might have proved hazardous.

Although relief of shoulder pain occurred in all but four patients, shoulder function was completely recovered in only two patients in phase 2 and in but one of four patients in phase 3. Hand pain was eliminated or diminished in all but one patient in phases 2 and 3, while a relatively poor improvement, closely approximating the responses at the shoulder, was noted in the hand signs. Swelling of the hand disappeared in all instances during treatment. Trophic changes were significantly improved in only two of the six patients who had them.

DOSAGE OF CORTICOTROPIN AND CORTISONE

Doses of each hormone were initiated at fairly high levels and regulated according to the patients' responses. In general 200 mg. of cortisone daily was given until definite improvement in pain, disability, and swelling appeared, usually in 3 to 10 days. Thereafter the dosage was reduced by small quantities until the minimum maintenance amount (75 to 100 mg. daily) was reached. A period of two to six months of maintenance at this level or lower was required before gradual reductions and test withdrawals indicated that treatment could be discontinued without return of symptoms. Corticotropin was administered in the same manner in half the doses for equivalent effects.

Complications occurred in two patients. A 60-year-old man with diabetes, arteriosclerosis, and coronary disease, while receiving corticotropin with excellent results, had sudden occlusion of arteries in both lower extremities below the femorals, with superficial and deep phlebitis of both legs. He was treated with anticoagulants, vasodilators, and later with lumbar sympathetic blocks, and eventually recovered. Another patient, accepted as a calculated risk owing to psychiatric disturbances, had a manic psychosis, and treatment had to be discontinued.[2a] Mild edema of the ankles and lower legs occurred in several cases during administration of the hormones but usually disappeared after dosage was reduced. All patients were kept on a salt-poor diet with the addition of potassium chloride in tablet form.

Our follow-up period varied from one month to one and one-half years, with an average of eight months. Two patients who had improved relapsed soon after therapy was terminated; they responded well to further treatment and showed a good final result. In spite of management in a hospital, with routine dietary regulation and continuous observation, the patients under therapy with corticotropin and cortisone needed careful regulation of dosage to avoid side-effects. The two important complications required termination of therapy. Two patients not included in this series have received hydrocortisone by local injection about the shoulder without appreciable improvement.

COMPARISON OF CORTICOTROPIN AND/OR CORTISONE AND STELLATE BLOCK

Although impressive results were seen in the patients receiving corticotropin and cortisone, on the whole the group that received stellate blocks showed a better response. The therapeutic action of the hormones, as with sympathetic nerve block, was uniformly better when treatment was instituted in the early stages of the condition. The two series are too small to reflect more than the trend of responsiveness to the methods of treatment. Further analysis, however, reveals that complete or partial relief of pain at the shoulder and hand took place in a significant number in both groups but in an appreciably higher proportion of those receiving stellate blocks.

Athough shoulder function was completely recovered within a short period in 12 of the 14 patients treated with sympathetic blocks, only 5 of 11 recovered this function in the group receiving hormones. Hand signs were greatly improved in 7 out of 14 receiving blocks, while 9 out of 13 receiving corticotropin and/or cortisone showed the same response. The slightly better effect of the hormones is due mainly to the almost constant responsiveness of hand swelling, more so than with sympathetic blocks. Trophic changes and contractures were not favorably changed by either mode of therapy. From the standpoint of time and the beneficial effects produced, patients receiving sympathetic blocks made more rapid improvement. No complications resulted from the stellate blocks. The only unpleasant sequel of the technique was occasional transient hoarseness or paratracheal (esophageal) discomfort on swallowing, which disappeared shortly.

As in one of the patients already mentioned, experience with cortisone and corticotropin has suggested the possibility of their fostering thromboembolic phenomena in some patients, especially those with vascular disease. In Russek's series of 17 patients with postinfarctional syndrome, no thromboembolic complication occurred.[3] Despite this optimistic experience, it probably remains an open question whether anticoagulants should be administered prophylactically before corticotropin or cortisone is given to patients with known vascular disease. This question was raised in our group by the recurrence of clinical and electrocardiographic signs of coronary occlusion in one of five patients with postinfarctional syndrome, who was receiving cortisone. This may have been a coincidence, but the considerations are too serious for generalization from our limited experience. The accepted contraindications and precautions for these compounds also apply to their use in the shoulder-hand syndrome.

Steroid therapy, which gives almost as good results as stellate blocks, apparently should be reserved for patients with the shoulder-hand syndrome who are sensitive to needle punctures in delicate locations and for those who are unresponsive to blocks, provided there are no contraindications. The great advantages of blocks are the rarity of contraindications, the usually shorter period of treatment without any further maintenance therapy, and the lesser likelihood of complications. A small number of patients who failed to respond to stellate blocks later were benefited by corticotropin or cortisone, but an approximately similar group unresponsive to the hormones were benefited by stellate blocks. Several patients, not included in these series, who were inadequately relieved by either blocks or steroids, improved when both forms of therapy were applied simultaneously.

[3] Russek, H. I.; Russek, A. S.; Doerner, A. A., and Zohman, B. L.: Cortisone in Treatment of Shoulder-Hand Syndrome Following Acute Myocardial Infarction, A. M. A. Arch. Int. Med. 91:487 (April) 1953.

Our results show that a thoroughly satisfactory and widely effective nonsurgical method of therapy still remains to be found for the management of the shoulder-hand syndrome, especially in its later stages. At this time, in view of the above considerations, sympathetic blocks still are regarded as the treatment of choice, with corticotropin or cortisone as the second method. Both measures may be carried out on an ambulatory basis, unless some complication makes hospitalization advisable. Special exercises and related measures for functional rehabilitation within the patient's tolerance are utilized along with blocks or steroids as a part of a well-rounded therapeutic program. In unresponsive patients suitable and fit for the procedure, sympathectomy remains as a last resort.

CONTROL OBSERVATIONS

Owing to the severity of the symptoms or the referral of patients by other departments or physicians for specific treatment, it was difficult to accumulate a series of cases under simple control measures to study the natural evolution of the shoulder-hand syndrome. Refusal of patients to accept one or both of the therapeutic procedures discussed and the unavailability of such therapy early in our studies of the shoulder-hand syndrome provided the opportunity to follow nine cases as controls on conservative management. Treatment consisted at various times of analgesics (salicylates, codeine, and barbiturates), electrotherapy, and exercises.

These patients were seen for six months to 13 years after presenting phase 1 or 2 of the disorder. Persons similarly treated in phase 3 were not thought suitable for comparison. Of these nine patients, one made a nearly complete recovery within four months. Most of the others were made more comfortable by the therapeutic program. Recovery of shoulder function appeared in all but one of the nine patients within 7 to 24 months. Resolution of hand swelling required three to eight months, but disabling alterations of the fingers with varying degrees of disability, of irreversible or apparently indefinite duration while under observation, were noted in seven of the nine patients.

As far as it is possible to conclude from this limited number of cases, these spontaneous developments in conservatively treated patients with the shoulder-hand syndrome revealed that sympathetic blocks or the administration of cortisone and corticotropin, in spite of failure in some cases, appear to be superior to nonspecific conservative measures. In each of the specifically treated groups the therapy resulted in more rapid control of the symptoms, quicker resolution of signs and disability, and less frequent and serious residual alterations of the affected parts. The most striking effect, and one probably appreciated by the patients, undoubtedly was the frequent relief or suppression of pain.

SUMMARY AND CONCLUSIONS

Of 126 persons with shoulder-hand syndrome seen by us to date, 91 were treated and followed up. Of the 91, 69 were subjected to blocks of the stellate ganglion, 13 received corticotropin (ACTH) and/or cortisone, and 9 were treated by simple conservative measures. Fourteen consecutive patients representative of the results from stellate ganglion block are compared with a series of 13 consecutive patients receiving corticotropin and/or cortisone. According to our observations, corticotropin or cortisone and stellate ganglion blocks constitute the most helpful nonsurgical therapeutic measures now available for the shoulder-hand syndrome.

The trends of responsiveness to corticotropin and cortisone in 13 patients with the shoulder-hand syndrome and to repeated blocks of the stellate ganglion in 14 patients are compared. Spectacular successes and unaccountable failures occurred with all methods. On the whole, sympathetic blocks gave somewhat better results. The responses to these two procedures were more rapid than and superior to those in the nine patients treated by simple conservative measures. Once a satisfactory result was obtained with stellate blocks, a period of maintenance therapy was not required, as with corticotropin or cortisone, to insure permanent benefit. Sympathetic block is contraindicated only by hypersensitivity to analgesic medication.

Cortisone and corticotropin therapy probably should be used only in patients unwilling to submit to sympathetic block or unresponsive to them, provided there are no contraindications to the use of hormones. Although a more satisfactory and more widely effective nonsurgical method of treatment of the shoulder-hand syndrome is desirable, our results so far suggest that sympathetic ganglion block is the treatment of choice, with cortisone and/or corticotropin as a second choice.

Intermittent Claudication of the Hip.—A cramp-like pain in the calf which occurs during walking and is promptly relieved by rest is almost certain to be correctly attributed to some interference with the normal arterial circulation of the lower leg. Because of the frequent association between pain in the calf and occlusive arterial disease, the term "intermittent claudication" has become almost synonymous with this particular symptom; however, typical intermittent claudication may occur in any muscle or group of muscles if the arterial blood supply is insufficient to permit their normal active use. . . . Typical intermittent claudication involving the hip, thigh or low back area, without pain in the calf region, was observed by LeFevre and associates in 26 of 47 patients with occlusive arterial disease involving the abdominal aorta or iliac arteries. . . . Intermittent claudication of the hip is not a diagnosis in itself, but rather a symptom, arteriosclerosis obliterans being the most common cause of this symptom. . . . Intermittent claudication of the hip may be mistaken for various orthopedic and neurosurgical diseases. A careful history of the character and duration of the pain and a careful examination of the peripheral circulation will always differentiate true intermittent claudication of the hip from any other disorder producing low back pain, hip pain, or sciatica. Aortography is a valuable diagnostic aid.—F. A. LeFevre, M.D., G. S. Phalen, M.D., and V. G. deWolfe, M.D., Intermittent Claudication of the Hip, *Cleveland Clinic Quarterly*, July, 1953.

CONGENITAL SPINAL MENINGOCELE

Rudolph Jaeger, M.D., Philadelphia

Congenital malformations of the spine resulting in grotesque protrusion of the intraspinal structures, with frequent associated paralysis of the bladder, rectum, and legs, are distressing and extremely serious lesions about which we have good reasons for acquiring more information. Scientific ignorance of such problems may lead to life-long blundering care of the patient from birth to death. The ever-lasting urinary and fecal incontinence, when present, can seldom be continually treated by a physician who has intimate knowledge of or experience with the neurophysiological abnormalities associated with the disorder because of its rarity. One of the most complete studies of this subject was made by Frazier [1] who made the pertinent comment that "spina bifida occurs approximately once in every thousand births, and of the infants thus afflicted, from 80 to 90% die during the first year, many even within a few days of birth, and of the small percentage remaining, the majority are mentally defective and physically crippled." His contribution should be read by every physician faced with the task of treating one of these little patients, because it clearly describes the fundamental anatomic defects that occur and because it presents an understanding of the basic physiological weaknesses caused by the imperfection.

This paper, based on an analysis of 68 case histories, is presented largely in reply to the question asked of me by a competent, widely experienced orthopedic surgeon. He asked, "Why don't you neurosurgeons keep the medical profession informed about the physiological disturbances in meningocele cases? It is only you who have the training and experience to clarify its complicated aspects and to outline rational therapy." The answer to the neurosurgeon's neglect of the problem is simple. Once the immediate problems of the removal of the meningocele and the treatment of the frequent hydrocephalus are accomplished they are only too glad to turn the paralyzed bladder and rectum over to the urologist and the deformed, crippled limbs to the orthopedic surgeon; they are at once relieved of the duty of personally caring for the unpleasant life-long residuals that are always present. I suspect that these latter specialists quickly refer the patients to the general practitioner.

GROSS APPEARANCE

The gross appearance of a spinal meningocele, with its covering varying in thickness from that of tissue paper to a hideous mass composed of thickened skin, subcutaneous fat, fascia, and snarled nerves, needs no detailed description. Associated lipomas, satellite cysts, telangiectatic angiomas, and overlying tufts of hair are common. Rupture of the thin covering is frequent with a resulting flow of spinal fluid through the opening. The lesion occurs most commonly in the lumbar spine (about 75%); the dorsal spine is the next most frequent site (15%). About 5% of all lesions are found in the sacrum and around 1% in the cervical spine. It is not unusual for two adjoining spinal segments to be involved in the malformation, and isolated meningeal cysts are found in the pelvis and mediastinum.

ASSOCIATED DISTURBANCES

The most striking disturbances associated with spinal meningocele are urinary and fecal incontinence, paralysis of certain muscle groups in the lower extremities, and sensory loss or impairment of all these structures.

Incontinence of urine, or uncontrolled urine, is the most distressing physical complication of the lesion; it obviously is caused by imperfect development of the cauda equina, or spinal cord, at the location of the deformity. Bladder paralysis occurred in 60% of this entire group of 68 patients, but it existed in 75% of those in whom the lesion was below the 10th dorsal segment. Only occasionally was there urinary incontinence when the lesion was above this level.

The evaluation of bladder function seems to be difficult for those who are not familiar with the paralysis of the bladder accompanying meningocele and other paraplegic states. It is quite customary for an infant with a meningocele to be referred to a neurosurgeon with the statement, "the bladder and bowel functions are normal," when, in fact, it has a complete loss of micturating and defecating control. How is it possible to clearly determine, by methods available to any physician, the actual state of these organs? As a matter of fact it is rather simple. If there is a perpetually wet diaper—the mother can determine this—the bladder is paralyzed; even in newborn infants, the bladder is completely and periodically emptied and there are long intervals during which the diaper is dry. Again, by observing the penis, urethrovaginal orifice, or the entire perineum, there will be noted a constant dribbling of urine that will increase with crying and straining and on abdominal pressure. A normal infant voids periodically as well as in spurts, and any clinician who has ever examined a baby boy without a diaper has undoubtedly observed this simple fact.

Fecal incontinence is not so disturbing or inconvenient, and it is not so likely to determine the life span as is bladder incontinence since the rectum can usually be kept clean of accumulated feces by periodic rectal irrigation. It can be very annoying, however, when the feces is liquid or semisolid, particularly in those patients having a low spinal lesion with complete loss of sphincter tone. Those lesions at a higher spinal level may allow fair spastic rectal sphincter action and consequently cause little bowel inconvenience. Actual rectal dysfunction occurs in precisely the same percentage as bladder incontinence. Perineal paralysis with loss of anal control is not difficult to ascertain. Simple inspection will reveal the flattened perianal region without clear definition of the radial mucous membrane markings. The anus is often open, and when stimulated at its margin with a sharp

---

From the Department of Neurosurgery, Jefferson Medical College and Hospital.

Read before the Section on Nervous and Mental Diseases at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

[1] Frazier, C. H.: Surgery of the Spine and Spinal Cord, New York, D. Appleton and Company, 1918, pp. 264-324.

pin prick the normal closing contraction is absent. Feces will be found on the diaper and in the anal canal; in fact, fecal dribbling occurs for the same reason and in the same manner as bladder dribbling. If there is any doubt, exploration with the fingertip will instantly detect the lack of sphincter tone and pain associated with the examination.

Paralysis of the arm muscles is exceedingly uncommon since it connotates a complete transverse cervical lesion that is incompatible with fetal maturity. Paralysis of the lower trunk, perineal, and leg muscles is common. The higher the meningocele on the lumbar spine the higher the level of muscular and sensory paralysis. When the lesion is in the lower dorsal segments, there may be complete paralysis of the legs, bladder, and rectum. The common muscular deficit, however, involves the perineum and the posterior aspects of the thighs and calves giving the infant a clubbed foot deformity because of paralysis. There may be power to flex the legs and the hip joint because the muscles that perform this movement have spinal nerves that originate at a higher level on the cord than the meningocele. The power to extend the foot at the ankle, knee, or hip is very weak or lost completely. Rarely a defect in development of the lumbar spine that is invisible externally causes simple unilateral clubbed foot. In one instance, the dissection of the lumbar spine of a clubbed foot, stillborn infant disclosed a single caudal root defectively arranged in an otherwise hidden meningocele type of malformation.

Sensory deficits occur concomitantly with motor paralysis and extend over the same precise neural segments. They can be mapped accurately by painstaking stimulation with a sharp pin. On passing the anesthetized area, there is pain, as indicated by movement and crying.

Various other physical deformities associated with meningocele are frequent and many times of equal concern to that of the spinal defect. Isolated meningoceles may be present (in the brain, mediastinum, and pelvis), and undescended testicles, imperforate anus, pyloric stenosis, cleft palate and harelip, dislocated hips, heart malformation, and any other possible congenital deformity may occur in the same patient with spinal meningocele. Hydrocephalus in mild and advanced forms occurred with spinal meningocele in 40% of this series. After operating on the meningocele, there were an additional 10% of cases in which hydrocephalus developed as a complication of the meningocele removal.

ANATOMY

The pathological anatomy of the lesion has been extensively studied, and its bearing on the functional disturbances are in direct relation to the lack of development of the spinal cord, or cauda equina. The lack of continuity between the brain and the peripheral organs and body structures through the spinal cord mechanism wholly and completely determines the degree of functional loss. A simple meningocele containing no neural element is comparatively rare. In the lesions considered here, 25% were of the uncomplicated saccular type, without evidence of anatomic or physiological involvement of the cord or nerves. These were oftenest found in the upper half of the dorsal spine or on the cervical spine. Massive lesions involving the cervical cord, comparable to those seen in the lumbar spine, are hardly compatible with life; therefore, the fetus seldom matures to survive birth. Those instances of massive anatomic involvement of the cord and cauda without major disturbances in innervation occurred in only about 10% of the cases. In this group are those lesions in which one or two minor roots of the cauda were involved or, as occurred in three instances, in which a nubbin of spinal cord protruded from it to affix its extremity to the dome of the meningocele. A careful dissection of the nerve structures in these cases may result in a complete cure without neurological complications.

A word should be said about spina bifida to clear the general mistaken concept of this unimportant part of the meningeal deformity. This term as applied to a spinal segment means only that there has been a failure in fusion across the posterior neural arch that has resulted in the appearance of two incompletely developed tiny (bifid) spinous processes side by side. This is a common finding at the first sacral arch, and it is not uncommon at the first cervical arch; it implies no abnormality of the cord or cauda equina beneath these defects. Spina bifida is of importance diagnostically only when found over several spinal segments and associated with obvious neurological defects. Meningoceles must have associated bifid spinous processes otherwise it would be impossible for the intraspinal neural element to reach the skin surface.

TREATMENT OF MENINGOCELE

Treatment of a meningocele requires restraint on the part of the surgeon and psychological conditioning of the parents for acceptance of the cruel blow that fate has dealt them. Since the grotesque mass is the most obvious problem to the parents, their reaction is to get the unsightly, shameful "thing" off now. Little do they realize its associated crippling implications. To a not too thoughtful surgeon the problem requires the same simple solution. We still see instances in which immediate removal is effected before mature consideration is given to either the psychological preparation of the relatives or plans for the future nursing care of the afflicted infant. It is my opinion that considered thought should be given to both of these aspects and, for that reason, it is well to delay surgery in those patients with paralysis of any kind until one is sure that the entire family, including the mothers-in-law, understand as clearly as possible that removal of the meningocele will have no effect on curing the infant of its bladder and rectal incontinence, paralysis of the legs, and mental abnormality. This the surgeon can be sure will take weeks or even many months. By taking a course other than this, the surgeon allows himself to be held responsible for the permanently crippled state of the patient. It appears to be a weakness of human nature for parents to blame chronic deformities on the physician who has performed an operation on the child, unless they have been skillfully prepared to assume the responsibility themselves before the operation. Nothing is gained by early operation because the small meningoceles without neurological deficits will not be harmed by waiting; the large protruding tight ones have associated hydrocephalus that should be treated prior to meningocele repair. To remove the meningocele early only aggravates the hydrocephalus. The large thin-walled protrusions, or those that have already ruptured and are draining, usually are associated with massive malformation of the neural elements, hydrocephalus, and mental impairment. A simple dressing with a "doughnut" type of protection around the mass is sufficient to prevent rupture. If the lesion has already ruptured, then it should be covered with an ointment dressing and treated as any other open wound. If one wishes to prevent meningitis, antibiotics should be given. Whether the surgeon is morally obligated to close open draining meningoceles to prevent infection is a philosophical question that one cannot answer dogmatically. Generally speaking, it is a physician's Hippocratic duty to preserve life and prevent suffering, but how can one be sure that he has selected the right course of action when the immediate saving of life may mean life-long suffering. In certain instances, the preservation of life is a blessing from heaven to no one, and so it often seems in the case of a mentally defective hydrocephalic or paraplegic infant "cured" by a skillfully performed meningocele operation. The surgeon is always obligated to make the decision of when to operate and how the procedure is to be executed. Above all else he must be certain that he is not being hired as the "lord high executioner."

Certain general rules may be used to guide the surgeon in making the decision of when to operate. It is better to err on the side of delay than to operate too soon. Hydrocephalus, if absent, is less likely to be a complication of late meningocele removal. It has also been observed that hydrocephalus, if present, tends to subside spontaneously as an infant approaches one year of age and that there is little likelihood of it developing after the infant is 18 months old; therefore, if there appears to be any tendency to hydrocephalus or if the meningocele is tight, it is better to wait until these states have subsided. This means that operation should not be performed before the infant is one year old. Small soft saccular meningoceles, with no evidence of hydrocephalus but with minor neurological involvement, may be operated on when the patient is five or six months of age. The cautious surgeon will even extend this age limit. Meningoceles that are soft and have no associated abnormal neurological finding may be operated on when the infant is sturdy enough to withstand the procedure, but, again, it is better to wait until the third or fourth month.

OPERATIVE PROCEDURE

The actual technical details of a meningocele operation are of no great concern. Various methods of turning in redundant underlying layers of the sac have been described but probably have no advantage over procedures that do not emphasize such unnecessary details. If hydrocephalus appears after removing a meningocele, it is unlikely that any technical anatomic repair that has been devised could have deterred its development. There is sufficient evidence to substantiate the theory that the meningocele absorbs some cerebrospinal fluid, but it is technically impossible to retain layers of the sac and at the same time remove it, leaving a fluid-tight wound. Occasionally it will be possible, and probably advantageous, to cover the spinal defect with lumbar muscle fascia before suturing the skin. Attention to the fundamentals of excision of the mass, preservation of cord structures, release and reapposition of separate nerve ends, and a water-tight closure with fine sutures are, of course, essential. Bungling, careless surgery can irreparably ruin important nerve roots or the spinal cord in cases in which they are attached to the dome of the meningocele.

Care of the meningocele patient after all corrective operative measures are completed is extremely important and must be carefully planned since it must extend throughout life. The life expectancy element is basic in long-range planning, and yet it can be appreciated that, in dealing with so many grades of similar malformations, the prognosis automatically becomes as variable as the seriousness of each deformity. Obviously a simple meningocele without neurological deficits and other gross malformation should carry no operative mortality or death from late complications. Conversely most of those patients with large meningoceles, paralysis of the bladder and rectum, and possibly hydrocephalus or other massive deformities will die within the first year after birth. In between these two groups, there is a third group of patients with complete paralysis of the rectum and bladder, partial leg paralysis, and possibly some hydrocephalus and mental impairment in whom the prognosis is dependent entirely on bladder function and the degree and frequency of infection of the urinary system. It is this intermediate group for whom it it so important to plan carefully over many years. In reviewing the 68 patients of this group, which included all types of spinal meningoceles and other deformities, it was found that 35% were dead after a six month period. I am confident that this figure is entirely unreliable, because it does not include those numerous meningocele patients that die during the first two weeks after delivery for whom the neurosurgeon is never called in consultation and of whom there is no record. After the age of six months, it was impossible, without great effort, to locate enough patients for accurate statistical purposes.

Institutional care must be the only answer to the intellectually impaired patient who is unreceptive to mental discipline. The sooner those of this group are separated from their families the better. To continue the home care of an obvious mental defective is unfair to the entire household, and it does the patient no good. Those with leg paralyses must be under the care of an orthopedic surgeon for many years. Supportive braces can do wonders in enabling these children to ambulate, and the outlook for successful locomotion is particularly good because the back, abdominal, arm, and shoulder muscles are usually in excellent condition. There is no reason to start corrective leg maneuvers before the extent of the lower limb paralysis is apparent. Painless pressure ulcerations of the feet, buttocks, sacrum, and penis are annoying problems demanding constant preventive measures and treatment.

Urinary tract paralysis is the greatest single problem in the long-range care of the meningocele patient. It can be said that urinary retention is the only critical aspect of the malformation. Without it these patients should have the same survival expectancy as any other newborn infant. Care of the impaired bladder, then, becomes the all important concern as it does in any spinal paralysis state. In a physiological way, however, the urinary tract paralysis is more serious in the meningocele patient since most of the lesions involve the conus or cauda. At these points the parasympathetics are paralyzed; this prevents reflex contraction of the smooth muscle of the bladder, resulting in flaccid bladder and ureteral walls. This encourages stagnation, calculus formation, infection, and ultimately hydronephrosis and pyonephrosis far more serious than that which occurs in cord lesions at a higher level. It appears likely that any patient with a complete conus or caudal lesion that totally paralyses the autonomic nervous system to the bladder and ureters will be dead in less than 10 years no matter how excellent the urinary system care may be. Conversely, any patient with a complete lower cervical cord lesion should live indefinitely if the bladder outlet is of sufficient size to permit easy and constant drainage of the urinary content. There are, however, no reliable statistical figures to warrant such a dogmatic statement, particularly since we know so little about the segmental autonomic innervation of the kidney pelvis and ureter. The erect posture, with its increased lower intra-abdominal pressure, will encourage the bladder, paralyzed by a low spinal cord lesion, to empty more completely. During any prolonged period of recumbent bed rest, the bladder, ureters, and kidneys act as one large infected cesspool to form stones and gather infection.

From a practical standpoint, it is imperative that the bladder outlet be kept large, that its interior be examined by a urologist at intervals no longer than six months, and that antibiotics be given at any sign of infection as indicated by fever, chills, and a decrease in well-being. In the boys, the dribbling urine must be collected by a rubber bag into which the penis protrudes. In the girls, this problem is more difficult and can be met only by a retention catheter or diaper. The poor prognosis in cases in which there is total bladder paralysis from a meningocele can be appreciated, when I point out that I could not locate a single patient that had survived the first 10 years of life. In fact, I do not know of even one patient with a complete transverse myelitis from a meningocele who has reached adolescence.

SUMMARY AND CONCLUSIONS

A study of 68 case histories of patients with all types of spinal meningoceles shows that by far the greatest number of lesions occurred at the lumbar level (75%). Involvement of the cord was uncommon in the upper dorsal and cervical regions. Hydrocephalus was a complication in 40% of the cases. There was bladder, rectal, and leg paralysis in 60% of the entire group and in 75% of those with cauda equina lesions. Death occurred before six months in 35%, and no meningocele patient with marked bladder dysfunction has reached adulthood.

Congenital spinal meningocele with bladder paralysis is a serious disorder. Only a few persons with this disorder can ultimately survive its complications. A conservative attitude is desirable in the treatment of the lesion, since surgical reparative procedures seldom alter the prognosis. Careful psychological preparation of the parents, good general medical management, and long-range, well-planned nursing care are essential to the patient's comfort and health.

TREATMENT OF TUBERCULOSIS FIFTY YEARS AGO

CHAIRMAN'S ADDRESS

Joseph C. Placak Sr., M.D., Cleveland

We know a great deal more about tuberculosis today than we knew 20 years ago, and we shall know still more tomorrow. Even as we discard older authorities, however, it behooves us to acknowledge our debt to them. As has been said, "We see farther in our time only because we stand upon the backs of giants."

Nevertheless, the great studies of yesterday will be superseded, are being superseded, even as they are being used. They will continue to fade gradually from footnotes and from bibliographies as newer, more accurate knowledge comes into its own, and finally they will be of merely "historical interest," which is a polite way of saying that they will have become obsolete. This is of course right and necessary. To say that few studies of 50 years ago are of any real scientific interest today is merely to say that medicine has made progress. And yet a review of the activities of that far-distant time is not without interest, and I propose to reminisce about that far-distant day when the study of tuberculosis and I were young.

The period between 1900 and 1910 is of interest because, although medicine has changed a great deal since then, its practitioners and servants have changed very little. A really scientific interest in medicine was extremely rare in the United States before 1900, except for a few isolated and daring pioneers. After that date the rise of scientific medicine was extremely rapid. Much of this interest was naturally directed toward the battle with tuberculosis. In 1903 Cleveland got its first institution solely devoted to the care of tuberculosis patients, a remodeled hospital left over from the smallpox epidemic of the previous year. Three years later the city council was persuaded to buy a large tract of land for the construction of the first sanatorium designed for the treatment of tuberculosis. In 1902 the City of New York passed the first ordinance in this country requiring the registration of known cases of the disease. These two developments, which were direct predecessors of the later campaign for isolation, were probably as important as anything that happened in the period, but we did not think so then.

Read before the Section on Diseases of the Chest at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

Prior to 1900 tuberculosis had been in truth the "white plague," and its diagnosis was not far from being a death sentence. The standard treatment for the disease was an air-tight room, with the patient wrapped up in a featherbed and stretched out behind a red-hot stove. It was a question at times whether he died of tuberculosis or parboiling. Administration of beechwood creosote and whiskey three or four times a day was the commonest medication, but it was beginning to be viewed with disfavor by some, probably on account of the rumors one heard of patients being occasionally overtaken by spontaneous combustion. It is small wonder that the medical profession had made little headway against the multitude of old wives' remedies that one encountered. These remedies were generally based on the premise that the bacilli had a sense of smell; they included sleeping on manure piles, eating dog fat, a regular diet of garlic, and sleeping in a room with one or more savory goats. Physicians with their time-honored hotbox treatment were naturally scornful of this folk-lore, but it is likely that more than one old granny had a better mortality rate than the medical profession.

ADVENT OF FRESH AIR THERAPY

After 1900 hot stoves and featherbeds became increasingly antiquated, and fresh air became the rage. In retrospect this new approach seems as irrational as the older one. The remodeling of our former smallpox hospital consisted largely of the addition of sleeping porches, where patients spent a good deal of their time the year around. The stiff breezes that were the outstanding characteristic of this treatment perhaps protected the personnel of the establishment from tuberculosis to some degree, but pneumonia was a real hazard. Our first genuine, built-to-order sanatorium was constructed 12 miles from the city, and the motive behind the project was not isolation but country air. In wet weather two teams of horses were sometimes required to drag the wagon with the new patient through the axle-deep mud. But since our first principle of treatment was fresh air and then more fresh air, the hardships were cheerfully borne. The sanatorium itself, like most of those built at that time, was basically four lean-tos in the form of a square, with the center covered and heated as a concession to man's frailties; in this center were the sitting room, dressing rooms, and lockers. This was perhaps the only time in history when rubber boots were a part of the regulation equipment of nurses. Rounds were made at night with barn lanterns, and it was frequently necessary to literally dig the patient out of a snowbank to take his temperature.

All this seems remarkably naïve medicine today, and yet this fresh air craze was a most important development in the history of the fight against tuberculosis. The thesis that wintry blasts could adversely effect a tubercle bacillus was erroneous, but these early fresh-air resorts accustomed the public and the medical profession to the idea of sanatoriums for the treatment of tuberculosis. The gain was immense, even if we did not understand it at the time. Even more important, perhaps, was the great change in attitude that this innovation represented. Patients had been wrapped in featherbeds and curled around hot stoves for generations. There is no reason to suppose that this kind of treatment produced more cures in 1750 than it did just prior to 1900, but in 1900 doctors were beginning to be a little dissatisfied with a treatment that had such miserable results, time-honored or no. They were no longer willing to prescribe the traditional remedy and leave the outcome to providence. There was the growing feeling that tuberculosis was a challenge to medicine, as well as a disaster for the victim. The dissatisfaction with anything less than perfection, which is responsible for our progress in the last 50 years, began at that time. Our knowledge and techniques were defective, but our attitudes were those upon which medical progress will continue to depend. We found yesterday's mortality rates distasteful.

USE OF PHYSICAL ACTIVITY

The interest and enthusiasm that new ideas could command in that early decade were remarkable, perhaps the greater because a little naïve. The work of Paterson and Inman at the Fimley Sanatorium in England was discussed everywhere and widely imitated. In the view of these notable pioneers, an important aspect of treatment was the prevention of physical decay due to prolonged inactivity. Therefore, after a period of rest, the patient was put on a regimen of carefully regulated work. He would start with a child's shovel moving dirt for a short time each day. The length of time and the size of the shovel were increased simultaneously, until the patient was actually working off his keep with a full-sized implement. Wheelbarrows and other equipment were also carefully graded as to size. The collection of tools that this institution boasted was a nine-days wonder. In our own sanatorium the theory was put into effect in terms of plots of ground which the patients tilled under supervision, and in terms of athletics. We had a baseball team one year that was undefeated. Even more remarkable, not one patient died on the playing field. It would seem that Divine Providence has a special care for young and slightly inept scientists.

If there was one single great defect in our efforts in those days, it was our failure to realize the complexity and difficulty of scientific proof where the guinea pigs were necessarily human beings. We were unduly anxious to accept statistics that were favorable to a cherished technique, without a critical survey of other factors that might be entering into our results. A good many of us were willing to swear that fresh country air 24 hours a day, unsullied by nasty old smoke, was the most remarkable cure for tuberculosis known to man. This conviction was based on the evidence of our own eyes; the improvement in patients that was noted after only a few weeks or few months of this treatment was patently spectacular. I know of no one at that time who pointed out that the rest and nourishment that was a kind of side-effect of the country air might really be responsible for the results. It should have been obvious, particularly since a good many of our patients in those early days were abandoned, derelict alcoholics in whom malnutrition was probably as important to symptoms as the bacilli.

We had no idea at that time of the intangibles that so plague medicine. The very optimism with which we were beginning to confront the disease had an incalculable effect. When we opened our first sanatorium, all of our patients were far-advanced—so much so that no therapy was of any avail. Because of the notorious fatality of tuberculosis, physicians delayed diagnosis until the patient was at death's door, and most laymen were absolutely terrified of entering those portals from which so few emerged ambulatory. We had a very difficult time convincing the layman that the black bottle used to speed hopeless cases was a figment of his fright. As a consequence, the population of that first institution was beyond the help of anyone or any remedy. As the medical profession gained confidence during that 10 year period, however, the layman gained confidence, too. There is no doubt that the decreasing mortality rate of which we were so proud was due in no small measure to the fact that we were beginning to get cases before the patient was absolutely moribund.

FACTORS IN DECREASING MORTALITY

All during this period the tendency to earlier diagnosis operated, and no one really took it into account. Also rest and nutrition came to be a natural adjunct of every remedy. The result was a steadily decreasing mortality rate, which we attributed to everything under the sun but the responsible factors. These factors distorted our statistics and played hob with our attempt to understand, while they made real cures possible. As an example, we were not faddists in our interest in the work of Paterson and Inman; the results they got at that sanatorium were really excellent for that time. We did not attempt to evaluate the whole situation; we looked in the direction that these great pioneers were themselves looking, at the physical exercise. We presumed that this was the really significant factor in their success, without having any real evidence for this presumption. The same thing might be said of the frequent recommendation that patients go West and ride horses. I have no doubt that the escape from emotional problems, the improved nutrition, and the rest that usually accompanied this remedy did actually save a great many lives. But we attributed such success as we had to the jiggling the patient's lungs received as he dashed across the countryside. The great lesson in these experiences is this: A tuberculosis treatment can only be proved by the most exhausting sort of clinical trials. About half of the science attached to the art of medicine is the science of statistics, of analysis. We have abandoned the notion that periodic jiggling is an efficacious remedy for tuberculosis, but it would be optimistic to assume that we have completely abandoned that attitude of mind that lay behind our early faith in jiggling.

We need to cultivate suspicion. At one time physicians had a great deal of confidence in the medicinal properties of whiskey. I truly believe that in some instances, when it was administered by a pretty nurse with lots of confidence, it helped. As a matter of fact, I have seen men it helped. But we were perhaps unduly slow to take into account the confidence and the pretty nurse. Instead, we nourished the vague conviction that you could sometimes pickle the bug without pickling the man first.

Our efforts in those days had another marked characteristic; we were not primarily interested in long-term propositions. We clung desperately to the conviction that all disease, including tuberculosis, must sooner or later succumb to some simple remedy or some simple preventative measure. We expected to beat the disease all at once. We had, as an example, the utmost faith in the applicability of Pasteur's theories to all contagious diseases, and we were convinced that sooner or later the white plague would follow smallpox down the road of contagious diseases that no civilized man need suffer from. At one time, three-fourths of the conversation at meetings such as this one was concerned with the relative merits of various kinds of tuberculin: Koch's, Deny's, Gabrilovitch and Von Ruck's and Formanek's all had their defenders and their impressive case studies.

Since even today we do not quite know why tuberculosis should be so extremely difficult to control by vaccination, this early enthusiasm is understandable. Our interest in quick and spectacular results did not confine itself to such relatively reasonable presuppositions, however. All sorts of spectacular claims had their day. In 1909, Friedman's sensational cure for tuberculosis occasioned the greatest interest and enthusiasm. It had to do, as I recall, with some sort of serum from infected turtles. The details escape me; perhaps they made turtle soup out of the animals. In any case, it made headlines throughout the world, and Friedman was invited to this country to demonstrate his technique. The reactions to an injection of the stuff were understandably severe, and to the jaundiced and skeptical eyes which we had developed by 1909 positive results were not apparent. So Friedman's tuberculosis serum faded from public notice. When I was in Germany with the Army of Occupation in 1919, I inquired of Friedman and learned that his notorious turtles were infected by a tuberculous housemaid who had made a practice of expectorating into their pool.

As a consequence of this interest in quick results, the truly significant work that was going on in this period was considerably neglected. Use of x-rays was introduced to Cleveland medical circles in the early part of this period; Dr. Iddings was our first roentgenologist. It did not really create much interest. We did not see the possibilities of the technique because we were not primarily interested in early diagnosis as a procedure in tuberculosis control. To some degree, of course, this neglect was understandable. One of roentgenography's early trials in Cleveland involved an aged gentleman who had a severe choking spell. Since the x-ray plate showed a density in the mediastinum, and since an examination revealed his upper plate to be missing, a surgeon was called and the patient was operated on immediately. Unfortunately, the patient died and a housemaid found the missing bridgework under the patient's bed. This was not the kind of experience to create a great deal of trust in roentgenological findings.

Yet if we had been sufficiently concerned with the hard, the slow, the painful, but the sure approach to the problem of tuberculosis, we would certainly have seen the great possibilities inherent in use of x-rays. We were too concerned with a possible easy way, and early detection and isolation, the two techniques that are without doubt chiefly responsible for the low mortality rates that we obtain today developed as great therapeutic principles almost without our noticing.

INTERNATIONAL CONGRESS ON TUBERCULOSIS OF 1908

I am fortunate enough to have the proceedings of the International Congress on Tuberculosis of 1908 in my possession. The significance of this meeting was tremendous. Almost all of the great pioneers in the study of tuberculosis were there, and in comparison with the modest aims of this assembly the program of that conference was all-inclusive. There were 330 papers in all, which included 45 papers that had to do with animal tuberculosis alone. There were discussions on tuberculosis in infancy, opsonic index, serum diagnosis, surgery, and conjunctival and cutaneous reactions, construction of sanatoriums, the cost of tuberculosis, bacteriology, epidemiology, pathology, diagnosis, social aspects and treatment. At the conference there was one paper on fluoroscopy and two on use of x-rays.

One author, quoting from Dr. John B. Murphy's surgical oration made previously to the congress on the status of lung surgery of that time, stated that abscess of the lung, actinomycosis, bronchiectasis, gunshot wounds, and foreign bodies—thanks to a goodly number of collected results—were conditions warranting surgical treatment. Up to that time Murphy regarded surgery as having been of comparatively little benefit in tuberculosis. Cases of drained cavities were then, as now, in the literature, but Murphy was doubtless correct in stating that this procedure was attended with uncertainty. The opening of one cavity often meant that one or more neighboring ones were left unoperated. A review of the results of partial excision of pulmonary tuberculous foci and a partial excision of the lung was most discouraging. Murphy in the same oration advocated the injection of nitrogen into the pleural cavity to partially collapse and thus immobilize the diseased lung.

Another author quoting from the paper of Dr. Samuel Robinson of Boston, states that "the literature of the past ten years contributes little encouragement as to the results of excision. The cases of Tuffier, Lawson, and Doyen will stand practically alone as successful excision of tuberculous lung lobes. As a result of considerable animal experimentation, I have come to regard the removal of one or two lobes of a dog or rabbit as an operation often done with absolute surety of success. Mayer, Green, and Janeway would, I think, support me in this conviction, although our experimental successes in the past few years tend to undo our hopefulness for lung excision in the future. It is difficult to abandon the possibilities of such operations on tuberculous foci as willingly as we abandoned them 10 years ago. It must be conceded however that pneumonectomy in the human lung in the presence of adhesions is quite a different problem from the same operation in the normal animal. Professors Brauer and Sauerbruch of Marburg, men of considerable clinical and experimental experience, have recently courteously answered my personal inquiries on this subject. They are of the opinion that the excision method of approaching tuberculosis offers little encouragement for the future." Within recent years this old conception of lung surgery has been disproved.

From the standpoint of history, almost certainly the most significant paper read at the Congress was one by Dr. Mary Latham on pneumothorax. The lack of interest that greeted her presentation was almost complete; most of the audience left the auditorium long before she was finished.

These things are historical curiosities. But they are something more than that also. We today may disclaim any kinship with the top-hatted figure of 1850 who performed brutal operations in a long black tail-coat, but our kinship with the medical men of 1900 is unmistakable. We know more today, and perhaps we have learned painfully, a few of the hazards that attend any attempt to be scientific about man's ills. Perhaps 50 years of alternate hope and despair have been enough to produce a truly scientific skepticism so far as tuberculosis is concerned. But in other specialties the same impulse to short-range vision, the same impulse to accept consoling statistics at face-value, are certainly in evidence from time to time. The history of our fight against tuberculosis in these 50 years is heartening, but it is full of mistakes that could have been avoided and that it is foolish to repeat in our advance against other diseases such as cancer. The certain remedy, the vaccination, the easy and relatively inexpensive attack on disease are important, but equally important are those slow and expensive methods of diagnosis and prevention and treatment. These latter are the methods that have paid off so richly so far as tuberculosis is concerned.

Above all, this decade between 1900 and 1910 must be cherished for the vision that it has left us. If I might single out the most important event of that period, I would suggest that it was the International Congress of 1908. Outside of Dr. Latham's report, which was neglected, I do not recall any spectacular new findings reported there. But the spirit that this congress exemplified was the basis for almost every achievement that followed. In attendance there were the world's medical experts, united against a disease. Even more, these experts were backed by their respective nations. Frank Billings was president and President Theodore Roosevelt was vice-president of the congress, as was Grover Cleveland, and the President was host at a reception at the White House for the delegates. That conference represented mankind united against mankind's enemy if ever a conference did. And the contribution that such unity made to the fight against tuberculosis was indispensable. Without the growing trust of the layman, without the ceaseless interchange of findings and opinions across national boundaries, it is probable that we would soon have abandoned our belief in fresh air for the old hot-box.

This achievement in union we were perfectly aware of; President Roosevelt, in his letter to the convention, said: "The International Congress of Tuberculosis is in the interest of universal peace. In joining in such a warfare against a common foe, the peoples of the world are brought closer together and made to realize the brotherhood of man; for a united interest against a common foe fosters universal friendship. Our country, which is honored this year, as the host of other nations in this great gathering of leaders and experts, . . . should manifest its appreciation by making this Congress worthy of the cause of our guests and of ourselves. We should endeavour to make it the greatest and most fruitful Congress which has yet been held. . . ." These times are of great difficulty; new violence and new hatreds everywhere threaten the vision of unity that President Roosevelt enunciated for us in 1908. But we dare not forget that vision, no matter what the difficulty. Medicine itself depends on our faith.

2228 Woodman Dr.

CLINICAL NOTES

RAPID SIMPLE METHOD FOR DETERMINATION OF SERUM POTASSIUM

H. G. Keitel, M.D.
and
N. B. Keitel, M.D., Bethesda, Md.

The time, special techniques, equipment, and expense required for the analysis of serum potassium concentration by the flame photometric or other current chemical methods have prevented the wider and more frequent use of serum potassium measurements in the diagnosis and treatment of metabolic disturbances. The simple, rapid, turbidometric method described, which is readily applicable for clinical use, depends on the formation of a potassium sodium cobaltinitrite precipitate.

MATERIALS

The following materials are needed: (*a*) two Sahli hemoglobin pipets; (*b*) two standard microscopic culture slides; (*c*) one rubber-tipped glass stirring rod, with the rubber tip measuring 2½ mm. thick, 7 mm. wide at the base, and 2 mm. wide at the tip; (*d*) one portable clinical centrifuge; (*e*) one 6 by 6 in. (15 by 15 cm.) sheet of overexposed x-ray film or black piece of paper; (*f*) one standard potassium solution containing potassium chloride, 3 mm. per liter (equals 0.224 gm. per liter), and sodium chloride, 140 mm. per liter (equals 8.12 gm. per liter), and one standard potassium solution containing potassium chloride, 5 mm. per liter (equals 0.373 gm. per liter), and sodium chloride, 140 mm. per liter (equals 8.12 gm. per liter); and (*g*) 15% sodium cobaltinitrite ($Na_3Co[NO_2]_6$), (Bakers), chemically pure.

METHOD
